NEW EDITION

## OF INTEREST TO EVERY MEDICAL PRACTITIONER

A proper understanding of Physical Medicine is becoming increasingly essential in everyday practice

THE . . .

## British Journal of Physical Medicine

is the only British Journal dealing exclusively with Physiotherapy, which includes Actinotherapy, Electrotherapy, Radiotherapy, Manipulation, Remedial Exercises, Massage, Diet, etc

In view of the rapidly increasing recognition of the importance of Physical Medicine the Journal has been considerably altered both with regard to its editorial matter and also in size format and typography. The new British Journal of Physical Medicine while as in the past providing its readers with the latest and most authoritative opinions on all matters appertaining to physical medicine includes shorter essentially practical articles and a variety of other information designed to be instructive to the general practitioner

## To give you a better

# Therapeutic result...

In the treatment of all debilitating conditions and in diseases of malnutrition the foremost authorities are agreed that the source of radiation should as near as possible approximate the U V wavelengths found in the Solar spectrum. The shorter or non-terrestrial wave-band merely brings about a too rapid erythema before the longer and essential wavelengths have become fully effective. In the "BIOSOL" the wavelengths below 2900 AU are completely cut off by means of the 'DORNO' filter. When on the other hand a strong erythema is required—as in the treatment of skin diseases, the 'DORNO' filter (exclusive to the "BIOSOL") has only to be removed. In this way provision is made for the two wave-bands which correspond to the two classes in which cases for actino-therapy can be roughly grouped. The 'BIOSOL' thus rationalizes technique to quite a new degree and is the obvious choice for the modern clinic.

## Medical Men supervised the design of the Linia Belt

The Belt for correction of Ptosis, Obesity, Faulty Posture and for post-operation wear

It was on the advice of medical men that the Linia Belt was evolved, frequent tests by doctors were carried out before it was made available for sale. That is why it is the recognised belt for men's wear.

Made to measure for every case, the Linia Belt is prescribed for obesity, for various ptotic conditions, for post-operation wear, for wear by the older man during golf and so on. The front is of thin, non-elastic tuck, the back of strong elastic. It is fully adjustable by slide buckles.

### YOU CAN ORDER BY POST

Perfect fitting guaranteed or money refunded in full. We make a reduction of 2/ in the £ on purchases for personal use to members of the Medical Profession. May we send you a fully explanatory booklet?

### PRICES

Linia Belt including a Linia Tuck Strap. Popular Model 1 3/4 yds (Black 4 gns). The Linia Model in pure silk extra light quality 6 gns (Black 7 gns). Standard Model 2 yds COD 1/ extra.

★ We shall be pleased to forward a specimen Linia Belt for your examination on approval.

The Linia Belt is on Sale Only at

## DEAF AIDS

### When Should their Use be Commenced?

Until recently it was customary to recommend a hearing aid only when the degree of deafness was such as to make it impossible to hear direct speech. Now it is being observed that continued strain produces a slowness in hearing and a loss in mental appreciation of sound which are quite apart from the actual physiological degree of deafness. This loss of mental appreciation is more difficult to deal with than the degree of deafness and to a great extent accounts for the great divergency in results given by hearing aids in apparently similar cases. It is found that old users of hearing aids have retained the faculty of appreciation more than non users of the same degree of deafness and for this reason hearing aids are now being recommended much earlier than previously, i.e. when the first difficulty in hearing is experienced and the deafness

does not yield to medical treatment. The retention of mental appreciation of sound and the preservation of hearing are governed by the use of the highest quality hearing aid available. The obvious choice is the AMPLIVOX, the first and most widely used high fidelity hearing aid. I should be glad to send you full particulars of the AMPLIVOX hearing aids.

*A. Edwin Stevens*

## FOR EFFECTIVE CONTROL OF PAIN

AMONG the many and diverse analgesics which have been evolved by modern chemical research acetyl salicylic acid retains its reputation as one of the safest and most effective. Its tendency to liberate salicylic acid—the irritant properties of which are well known to physicians—has, however, caused many to hesitate to employ it as widely as it deserves. Exhaustive trial in hospital and private practice proves that "Alasil" definitely solves the problem of administering acetyl salicylic acid in an effective form being free from the risk of irritating the stomach or bowels or of causing general reactions.

*A supply for clinical trial with  
full descriptive literature sent  
free on request*

In "Alasil" the desirable therapeutic effects of acetyl salicylic acid are well exhibited by its calcium acetyl salicylate moiety while the presence of "Alocol" (Colloidal Hydroxide of Aluminium) a powerful gastric sedative and antacid, obviates any tendency to gastric irritation. The superior absorbability of "Alasil" over ordinary salicylate compounds and its freedom from the risk of liberating free salicylic acid in the stomach have been well proved by careful experimentation. "Alasil" can be prescribed with perfect safety to patients of all ages and in larger doses than ordinary salicylate compounds.

## 'Nestrovite' is made in 2 forms

### TABLETS & EMULSION

"Only those concentrates should be used whose potency is known"—  
B M J, Nov 2, 1935

The composition of 'Nestrovite' and the potency of the four vitamins, A, B<sub>1</sub>, C and D, are clearly stated on every packing. The preparation is reliable, palatable and not expensive, and is made in England. A 4½ fl oz bottle of Emulsion contains 36 teaspoonfuls each representing an average dose for an infant. The tablets are issued in boxes of 20 and 100.

the prevention of infection —

it is now generally agreed that dependence of the vitamin B complex may be related to increased susceptibility to certain kinds of infection.

(Proc. P. C. C. M. d. 1937 30 17)

A popular method of raising the vitamin-B content of the diet consists in the systematic administration of Marmite. This yeast extract is rich in all the vitamins of the B group, and is being increasingly prescribed for its health-promoting properties.

Marmite is ordered as a routine measure all the year round in private practice and in hospitals, schools and welfare centres, and when epidemics prevail its use is especially indicated. On account of its appetising flavour Marmite is appreciated by patients of all ages, but children find it a particularly attractive dietary adjunct.

## Oral Vaccine for the prevention of Colds and Influenza

Since Genatosa brand Oral Vaccine was introduced to the Medical Profession last Winter, extensive clinical and laboratory tests have shown that it establishes a high degree of immunity against colds and influenza, the oral vaccine has also proved successful in the treatment of chronic bronchitis and similar respiratory infections

This vaccine contains hemolytic streptococci, in addition to other organisms incriminated in the causation of colds and influenza infections. It has been found that the ingestion of the oral vaccine against colds and influenza also develops immunity to diseases caused by hemolytic streptococci

Particulars concerning Genatosa brand Oral Vaccine will be found in the new brochure on Vaccine Therapy which has recently been published by Genatosa Ltd. This booklet also gives information regarding a wide range of vaccines administered by hypodermic injection and the standard types of Local Immunity Products. A copy of the brochure will gladly be supplied to any physician on request

## SCHOOL CHILDREN ESPECIALLY . . . ARE FOND OF THIS PURE FRUIT JUICE

GOOD work, as every doctor knows, is very often dependent upon good health. And a well regulated diet is important for maintaining good health.

Dole Hawaiian Pineapple Juice is the natural juice of sun ripened, Dole grown pineapples. It contains no added sugar or preservatives of any kind.

The exclusive Dole Fast Seal Vacuum Packing Process returns, to a high degree, those important fresh fruit constituents found in the ripened pineapple so valuable, not only to growing children, but to adults as well! Also this tangy, tropical juice is a natural source of vitamins A, B and C. That's why, with schooltime when parents are asking about diets and menus for their children you can recommend with assurance pure unsweetened Dole Pineapple Juice—the original pineapple juice from Hawaii.

J. K. Husband & Co. Ltd., 10 Finsbury, London, E C 3

**THE LEI WOMAN**—An old Hawaiian custom ever new is the habit of decorating departing or returning friends with beautiful wreaths of native flowers. The fragrant ulu, maile, plumeria, pikake and ginger are used extensively in the making of leis. It is a picturesque sight on steamer days to see the native women with their skilful hands weaving the fragrant garlands.

### HERE IS A TYPICAL ANALYSIS OF DOLE PINEAPPLE JUICE

Moisture	85.3%	Crude Fibre	0.02%
Ash	0.4	Titratable acidity as citric acid	0.9
Fat (ether extract)	0.3	Reducing sugars as invert sugar	12.4
Protein (N x 6.25)	0.3	Carbohydrates other than sugars (by difference)	0.38

**P.S.** We would like you to enjoy a long cool glass of this refreshing juice! Write to us on your letterhead and we will send you a sample tin free.

## Treatment of Pertussis by the Intranasal Instillation of 'TOPAGENE' Mulford

**'TOPAGENE'** Pertussis Bacterial Antigen is indicated in the specific treatment of pertussis by intranasal instillation. It is a sterile solution of soluble antigenic substances derived from recently isolated phase I culture of *H. pertussis*. Each c.c. represents the antigenic substances derived from 20,000 million organisms. Its use clinically has resulted in definite cessation or amelioration of the paroxysmal cough and a decrease in the duration of the disease.

Slingsinger, in *Journal of Pediatrics*, 9 42, 1936, states that 'We feel that

the high percentage of favourable results and the simplicity of the method of treatment definitely class this intranasal antigen as a valuable therapeutic procedure in the treatment of active cases of whooping cough.'

The experience of Gold reported in *Journal of Pediatrics* 10 641, 1937 shows definite benefit in 85% of the cases treated early in the paroxysmal stage of the disease.

'Topagene' Pertussis Bacterial Antigen is supplied in 5-c.c. vial fitted with pipette bulb stopper.

*Descriptive literature sent on request*

# Convalescence

In convalescence a tonic is required that will co-operate with, and augment, the natural recuperative powers of the body, rather than one which will have only an immediate stimulating effect. In the latter case there is always the danger of disappointment, due to an artificial improvement that the natural powers are unable to stabilise

Medical evidence extending over many years has established the value of Sanatogen in promoting convalescence. In "The Elements of Pharmacy, Materia Medica and Therapeutics", Sir William Whitla writes —

*The interesting and valuable researches conducted by Tunncliffe and Beddoes upon metabolism, in which Sanatogen was experimented with, establish the fact that its organic phosphorus is almost entirely assimilated when the food is administered in the amount necessary for the needs of the body. When given in addition to other food, the amount of nitrogen and phosphorus retained in the organism is increased, the tissue metabolism is more complete, the constituents of the ordinary food being more thoroughly utilised, appetite is increased and the body weight augmented."*

Similarly gratifying observations are constantly being notified, and, as Sanatogen is entirely free from fats, sugars and carbohydrates, it can safely be prescribed in all types of cases. It is rapidly and easily digested and assimilated, even in cases exhibiting severe gastric inflammation, and for this reason it is a valuable addition to enemata. It can be added to any non-acid beverage or food, and, consequently, monotony in its administration can always be avoided.

# The Vicious Circle in Haemorrhoids

## Effectively Broken

First there is marked relief from pain and irritation. The suppositories afford this alleviation not by narcotic or analgesic drugs but by their emollient and protective effect.

Under this soothing influence inflammation subsides, thus congestion is reduced; then pressure-pain disappears and the patient obtains genuine relief from the most distressing symptoms. The tendency to bleeding diminishes as venous stasis is relieved and the return circulation is improved.

By softening the faeces the suppositories promote easy evacuation, so the patient loses his fear and is helped back to regular bowel action.

This sequence of good effects follows without the occurrence of any unpleasant, dangerous or systemic disturbance.

In this entirely mechanical and rational way, Anusol Suppositories provide freedom from the distressing symptoms of haemorrhoids and other inflammatory and painful conditions in the ano-rectal region.

## REPORTS AND ANALYSES

### MOUSSEC

(MOUSSEC LTD., 175-6, PICCADILLY, W.1)

This is a sparkling wine of the champagne type prepared from imported grape must and fermented in this country by suitable selected champagne yeasts. The treatment of the wine during and after fermentation is the same as carried out in the well-known wine houses in France. When analysed the following results were obtained:—

Alcohol (by volume)	12.0	per cent.
Equivalent to proof spirit	20.65	"
Total extractives	3.93	"
Consisting of—		
Invert sugar	1.97	"
Cane sugar	0.29	"
Fixed acidity (as tartaric acid)	0.51	"
Mineral matter, &c.	1.16	"
Volatile acidity (as acetic acid)	0.06	"

The wine has the appearance, composition, and general properties of an ordinary dry French champagne. It is light and pleasant to the palate, and has an agreeable aroma. The manufacturers would seem to have succeeded in making, in this country, an attractive and wholesome wine closely resembling the imported product.

THE LANCET, JULY 6, 1935

## • When convalescents need a *pick-me-up*

Moussec can be recommended with confidence. Moussec is sparkling wine produced from selected champagne grapes, fermented and matured in this country by the authentic champagne process. A special process of refinement gives to Moussec a purity and digestibility specially suited to invalids. It provides the valuable stimulus of champagne at an everyday price. The shilling "baby" bottle, which fills one champagne glass, provides daily Moussec in convenient form and keeps the wine keen and full of life until wanted for use. (Other bottlings up to 6/6)

*A copy will gladly be sent to any Doctor who writes to Trufood Ltd, (Dept 1118),  
Bebington, Wirral, Cheshire*

# Laxatives for Children

The choice of laxatives for children is governed by many exacting considerations. To aid the Physician in assessing the merits of Andrews Liver Salt, its main characteristics are briefly listed below

- 1 The dosage is easily adjusted according to age
- 2 It is pleasant-tasting. Children accept it readily
- 3 The taking of Andrews is not followed by the griping or other pains that often lead to psychological revulsion against the more drastic purgatives. Its laxative action is extremely mild and is due to the presence of magnesium sulphate and other salts, which increase the fluid content of the bowel by Osmotic action and so lead to painless easy evacuation
- 4 Andrews has a soothing effect on the stomach and a physical cleansing action on the stomach walls which breaks up any unhealthy coating of mucous. It is also useful as a gastric sedative in the bilious attacks to which many children are prone
- 5 The action of Andrews is not limited to the elimination of waste, it also corrects excess acidity, stimulates the flow of bile and generally aids the digestive system
- 6 Andrews creates no dependence on artificial aid, but can be discontinued when the need for it ceases

## DOSAGE FOR CHILDREN

*From two years of age, it is safe to start with  $\frac{1}{2}$  teaspoonful and to increase the dose as necessary for older children*

BELIEF IN THE HEALING POWER OF CERTAIN MAGIC STONES WAS PROBABLY TRANSMITTED FROM CELTIC PAGAN TIMES TO MODERN IRELAND—The dumb-bell-shaped stone about five inches long here reproduced has been preserved in Donegal and used in religious medical treatment whereby the patient is given draughts of water in which the stone has been steeped. This stone is said to have been sent to America to heal an emigrant Donegal man. Such stones are borrowed, retained until cure is effected, and then returned with solemn faithfulness. They are believed to be particularly effective in cases of hydrophobia and diseases arising from fairy or demoniacal influence, especially when accompanied by the incantation of magic words. Fairy-struck cattle are similarly treated.

## THE ALKALOID EPHEDRINE\*

By

J. H. GADDUM, Sc.D., M.R.C.S., L.R.C.P.

Professor of Pharmacology, University College, London

The alkaloid ephedrine is present in extracts of various plants belonging to the genus *Ephedra* which all grow in roughly the same latitude in Northern China, Northern India and Spain. One species has been used as a drug in China for about 5000 years under the name of ma huang. The plant consists almost entirely of bundles of green stems lying parallel without much branching. The leaves are reduced to small dry scales arranged in twos or threes round the stem at intervals, so that the plant looks rather like an equestrian. In actual fact the ephedras are gymnosperms and are therefore related to the pines and firs whereas the equestrians are not flowering plants at all and are very distinct relations of the ephedras.

The chemical structures of ephedrine and pseudo-ephedrine are here shown. These alkaloids both of which

surviving reference was published about 2000 years later. This represents a big gap in the literature but it is probable that many references from this period have been lost. After the beginning of the Christian era the rate of publication increased from about one paper per century to four papers a century in the period 1800 to 1880.

Chart showing the history of scientific work on ephedrine.

are present in the green stems of some kinds of ephedra are optical isomers of one another and closely related to adrenaline. The molecules of ephedrine and pseudo-ephedrine each contain two asymmetric carbon atoms. There are therefore four optical isomers. The two laevorotatory isomers are included in the formulae given here. The dextro isomers are the mirror images of these. The difference between ephedrine and pseudo-ephedrine depends on the position of the two asymmetric carbons relative to one another and is represented graphically by drawing  $-NHCH_3$  and  $-OH$  near to one another in the case of ephedrine and opposite to one another in the case of pseudo ephedrine. l-ephedrine and d-pseudo ephedrine are the natural isomers and are more active pharmacologically than the other isomers.

### Early References to Ma Huang

The history of scientific work with ephedrine is shown graphically in the chart which is based on a bibliography by B. E. Read showing all the papers on the subject up to 1934. The rate at which papers on ephedrine appeared is plotted against time. The first pharmacological experiments were carried out in China in 2760 B.C. by the Emperor Shen Lung who tasted all the drugs in the pharmacopoeia and classified them accordingly. Ma huang was classified as a medium drug. The next

A famous pharmacopoeia written in China in A.D. 1394 says that ma huang is of use as a circulatory stimulant, diaphoretic, antipyretic and sedative in cough. Modern observations confirm most of this. Ephedrine does stimulate the circulation under certain conditions and has been found beneficial in whooping cough. Its diaphoretic effect has been observed in man but attempts to demonstrate it in animals have been unsuccessful.

### Modern Literature

After 1880 the rate of publication increased so rapidly that it is necessary to plot the results on a different scale.

Ephedrine was isolated by the Japanese worker Nagai (1887) and given the name by which it is known today. Pharmacological investigations showed that large doses had toxic effects and ephedrine acquired a reputation as a dangerous poison. Its medicinal action was discovered and added in 1892. Takahashi and Miura (1892) came to the conclusion that ephedrine dilated the pupil by stimulating the sympathetic nerves. It is remarkable that they should have reached this conclusion so long ago before anything was known of adrenaline or even about the properties of suprarenal extract. The only other substance the kidneys secrete which has a similar action was cocaine. At about the same time ephedrine came on the market in Europe as a mild stimulant and was almost entirely not employed for other purposes and was soon discarded. For many years little research was done except by chemists who worked out the details of the chemical structure and had synthesised all the optical isomers by 1921.

\*S. Dines Ringer Memorial Lecture delivered at University College Hospital Medical School, March 8, 1938.

The pharmacology of ephedrine was reinvestigated in Japan by Amatsu and Kubota in 1917. It was shown to have sympathomimetic effects like those of its chemical relative adrenaline. Ephedrine was put on the market in Mukden as a remedy for asthma but since the results were published in Japanese they attracted no attention in the Western world, and were even unknown to Chen and Schmidt when they started to work on ma huang in 1923. A Chinese druggist told them that this was a really active drug and would be likely to prove interesting. They therefore made extracts of the plant injected them into dogs, and observed the resulting rise of blood pressure. They isolated the alkaloid and showed that it had adrenaline-like properties before they discovered that ephedrine had been isolated and studied before. Nevertheless this work of Chen and Schmidt had a very important effect, because it aroused interest in ephedrine and stimulated the production of papers. Their original paper was published in America in 1924. By 1927 the rate of publication had risen from less than ten papers per year to about 150. Thereafter the rate slowly fell, but more papers are still produced each year than before Chen and Schmidt's article appeared.

Ephedrine provides an example of the practical application of pharmacological discoveries in clinical medicine. It is interesting to note that fundamental observations on its action were made on three separate occasions before they caught the imagination of the world. Once the imagination was caught the demand for ephedrine was great, and the world now consumes about ten tons a year—corresponding to about 1,000 tons of ma huang.

Synthetic ephedrine was introduced in 1927—the year when interest in ephedrine was at its height—under the name of ephedrin. This preparation consists of a racemic mixture of the two optical isomers and is therefore slightly less active than the natural *laevo*-ephedrine. Competition brought the price down from 33s 4d an ounce in June 1929, to 5s 10d an ounce a year later and 2s 6d in 1936. Thousands of tons of ephedra were exported from China, India, and Spain, mainly to America, where very large stocks are held now, and someone must be making a lot of money, because the wars in Spain and China have sent the price up to about 12s an ounce. Synthetic ephedrine has thus come into its own and it has become economically possible to sell synthetic *laevo*-ephedrine which is presumably equivalent in all respects to the natural product. This fact has probably kept the price of natural ephedrine from rising still higher.

### The Pharmacological Effects of Ephedrine

The pharmacological effects of ephedrine resemble those of adrenaline in many ways. For example, under suitable conditions ephedrine raises the blood pressure by constricting the blood vessels and stimulating the heart. It dilates the pupil, dilates the bronchi, inhibits the intestine, and raises the blood sugar. In large doses it has various other effects, which have been attributed to an indiscriminate stimulation of smooth muscle and to stimulation of autonomic nerve ganglia. I am not concerned with these effects now, nor with its action on the central nervous system, but with the adrenaline-like action of small doses. The actions of the two drugs resemble one another in many ways but various differences have been noticed. I propose to give a list of these now and to discuss them more fully later.

1 Ephedrine is more stable and has a more prolonged action than adrenaline and unlike adrenaline, it is effective when given by the mouth.

2 Section of the sympathetic adrenergic nerves to certain tissues followed by degeneration increases the effect of adrenaline and diminishes that of ephedrine. An injection of cocaine has similar effects.

3 Ephedrine has often been found to have much less action on isolated tissues than might have been expected from its effects in the body.

4 If the same dose of ephedrine is given repeatedly the effect diminishes with each successive dose. This is not true of adrenaline. This immunity lasts for only a few hours. Rabbits which have received injections of ephedrine every day for several months still react to ephedrine with a rise of blood pressure (Ruhl, 1929).

It is evident that although the actions of ephedrine resemble those of adrenaline superficially the two actions are not exactly the same, and various workers have come to the conclusion that the two drugs act on different parts of the sympathetic mechanism. I want to tell you of some new observations, and of a new theory which explains some of the peculiarities of the action of ephedrine.

### The Cholinergic and Adrenergic Nerve Groups

Before discussing these new facts I propose to recall to your minds certain recent advances in our knowledge of the mode of action of motor nerve endings. Evidence has been advanced that most, if not all, motor nerves produce their effects by liberating a chemical substance at their ends. This chemical substance carries the impulse across the synapse and, by its pharmacological action, produces the effects which were formerly supposed to be produced by the nerve itself. Motor nerves can be divided into at least two classes according to the nature of the chemical substance liberated. Most motor nerves liberate acetylcholine, but some of them liberate adrenaline or a closely allied substance. Sir Henry Dale has suggested that the former group should be called cholinergic and the latter group adrenergic. These words supplied a real need and have spread all over the world.

Some years ago, when I was working in Sir Henry's laboratory, I helped to identify the substance liberated at cholinergic nerve endings as acetylcholine. Chang and I (1933) showed that, by suitable pharmacological tests it was possible to distinguish acetylcholine from other choline esters, and then Feldberg and I applied these tests (1934) to the substance liberated in a sympathetic ganglion and identified it as acetylcholine, as distinct from other choline esters. Later similar results were obtained in experiments with other nerves, and more recently I have been trying to apply tests to discover whether or not the substance liberated by adrenergic nerves is adrenaline. This question is particularly interesting to us because the theory that nerves liberate adrenaline was first advanced by Professor T. R. Elliott in 1904. It is also particularly important because Cannon and Rosenbluth (1937) have presented evidence that two different substances are liberated on stimulating different kinds of adrenergic nerves. They believe that both substances are similar to adrenaline, but that neither of them is identical with it.

### Substrate Competition

The experiments with acetylcholine were made much easier owing to the discovery that eserine (physostigmine) preserved acetylcholine from destruction in the body. In the absence of eserine the acetylcholine liberated at nerve endings was apt to be destroyed before it could be detected, but when eserine was added the acetylcholine was preserved and the experiments were successful. The enzyme which destroys acetylcholine is known as choline esterase and it is probable that the eserine acts by combining with choline esterase and blocking it up (Easson and Stedman, 1936). The eserine molecule is in certain respects similar to the acetylcholine molecule and choline esterase does not seem to know the difference. The molecules of enzyme combine with eserine which is comparatively stable, and are therefore no longer free to devote them

selves to the destruction of acetylcholine. This chemical phenomenon is known as substrate competition. A substance which would preserve adrenaline in the body in the same sort of way that eserine preserves acetylcholine might therefore be expected to facilitate experiments with adrenergic nerves as eserine has facilitated experiments with cholinergic nerves. Such a substance would probably be similar in chemical structure to adrenaline but more stable. There is reason to believe that ephedrine acts in this way.

The adrenaline molecule may meet its end in various ways. The catechol group makes it unstable. In watery solution its tail curls up and becomes attached to its head forming a red indole derivative. This change is inhibited by blood and is not the only fate of adrenaline in the body which contains several enzymes capable of destroying adrenaline in different ways. Various workers have recently been drawing attention to one particular enzyme known as amine oxidase which destroys adrenaline and various other amines by removing the nitrogen. Blaschko, Richter and Schlossmann (1937) have shown that ephedrine is not destroyed by amine oxidase but that in the presence of ephedrine the enzyme is prevented from destroying adrenaline. They attribute this action like that of eserine to substrate competition.

These experiments of Blaschko, Richter and Schlossmann were carried out with minced tissues and the rate of destruction of adrenaline was calculated from measurements of the increased oxygen uptake due to adrenaline. The results clearly show the presence in certain tissues of an enzyme which destroys adrenaline and which is inhibited by ephedrine. They throw no light on the part played by the enzyme in the body but they show that if this enzyme should turn out to be the agent which destroys adrenaline when it has produced its effect ephedrine would be likely to inhibit this destruction and play a part similar to that played by eserine at cholinergic nerve endings. My main purpose is to discuss the evidence for the theory that amine oxidase and ephedrine do in fact act in this way. This theory explains some of the peculiarities of the action of ephedrine and I therefore propose to return to these peculiarities and discuss their relation to the theory.

#### Peculiarities of the Action of Ephedrine

In the first place the fact that the actions of ephedrine are more prolonged than those of adrenaline might be explained on the theory that the action of adrenaline is normally controlled by the action of amine oxidase and that ephedrine owes its prolonged action to its immunity to this enzyme. The prolonged action of ephedrine could however be explained in other ways since ephedrine is normally resistant to other destructive agents besides amine oxidase.

In the second place experiments on the effect of the degeneration of nerves confirm the theory that some of the actions of ephedrine resemble those of eserine. After degeneration of its nerve supply the pupil becomes more sensitive to acetylcholine and adrenaline but much less sensitive to eserine and ephedrine. After degeneration of the nerves the liberation of chemical transmitters presumably ceases so that substances whose actions depend on preservation of the transmitter naturally lose their effect. The action of small doses of ephedrine on the cat's nictitating membrane on the other hand is increased by degeneration of the nerves (Bulbring and Burn 1937). In this case ephedrine presumably acts exactly like adrenaline.

The third peculiarity of ephedrine which I mentioned is the fact that it often has less action on isolated tissues than might be expected from its activity in the body.

Schaumann (1928) suggested that this difference might be due to the presence of adrenaline in the body and its absence in isolated tissues. He found that when adrenaline in a concentration of one in ten millions was added to the Ringer's solution perfusing a frog's legs the addition of a similar concentration of ephedrine caused marked vasoconstriction. In the absence of adrenaline these concentrations of ephedrine had no effect. Burn (1932) obtained similar results when dog legs were perfused with blood. Incidentally Schaumann observed that when high concentrations of ephedrine were added to perfusion fluid containing adrenaline the ephedrine caused vasodilatation. This observation falls in line with various others which show that *high* concentrations of ephedrine antagonize adrenaline. The observation led Schaumann to the discovery that the injection of ephedrine increased the effect of the subsequent injection of adrenaline on the blood pressure of rabbits and dog. Similar results have been obtained by others. Csepai and Dolezal (1928) found that ephedrine increased the effect of adrenaline on the blood pressure of man. On the other hand Curtis (1929) observed that large doses of ephedrine antagonized the effect of adrenaline on the blood pressure of dog. Reinitz (1929) found that low concentration of ephedrine increased the effect of adrenaline on the rabbit's uterus. High concentrations had the opposite effect. Pak and Tang (1931) discovered that the application of ephedrine to a rabbit's conjunctiva sensitized the pupil to the subsequent local application or intravenous injection of adrenaline. Kwiatkowski and I have recently seen similar effects in a frog's heart, a rabbit's ear and a cat's nictitating membrane.

Low concentrations of ephedrine have thus been shown to increase the actions of adrenaline in much the same way that eserine increases the actions of acetylcholine. This effect of eserine is generally attributed to the inhibition of choline esterase but so far as I know no one has suggested that the corresponding effect of ephedrine is due to the inhibition of an enzyme. Now that Blaschko, Richter and Schlossmann have demonstrated the inhibition of amine oxidase by ephedrine *in vitro* the evidence is as complete in the case of ephedrine as it is in the case of eserine. The possibility of other explanations must however be borne in mind.

These results provide a new method of studying the mechanism at an adrenergic nerve ending. Eserine increases the action of cholinergic nerves presumably by inhibiting the destruction of the acetylcholine which they liberate. Kwiatkowski and I have found that ephedrine has a similar action on the adrenergic nerves in a frog's heart, a rabbit's ear and a cat's nictitating membrane.

#### The Effect of Ephedrine on Adrenaline and Adrenergic Nerves

I hope I have convinced you that, under appropriate conditions ephedrine potentiates the actions of both adrenaline and adrenergic nerves. If this effect is due to the protection of adrenaline from destruction ephedrine should increase the amount of detectable adrenaline liberated on stimulation of adrenergic nerves. Kwiatkowski and I have obtained direct evidence of this in experiments with the perfused ears of rabbits. For these experiments the ear was perfused with the solution known as Locke-Ringer by means of a special device which ensured that the rate of flow was practically constant and was not affected by stimulation of the nerves. A sensitive colorimetric test for adrenaline devised in my laboratory by F. H. Shaw (1938) was applied to the outflowing fluid. This test is not affected by ephedrine and makes it possible to distinguish adrenaline from closely allied sub-

stances When the nerves were stimulated in the presence of ephedrine an adrenaline-like substance was detected in much higher concentration than had been possible without ephedrine

These results show that ephedrine protects the substance liberated by the nerves, and support the theory that the sensitization of adrenergic nerves is due to this effect. Since amine oxidase is the only enzyme which has so far been shown to be inhibited by ephedrine they suggest that this enzyme is present near the nerve endings and constitutes the normal mechanism for destroying the chemical transmitter. I think, however, that the main importance of the results is that they have made it possible to obtain the chemical transmitter in higher concentrations than before and to discover something of its properties. It has been suggested, for example, that the substance liberated by adrenergic nerves such as those in a rabbit's ear is not adrenaline, but noradrenaline. By means of a specific modification of the colorimetric test this possibility has been excluded.

### Ephedrine and Adrenaline Antagonism

I have said nothing so far about the explanation of the fourth peculiarity of ephedrine—the diminishing effect of successive doses—nor about the action of large doses in antagonizing adrenaline. I believe that these effects are two aspects of the same phenomenon. Schaumann observed both effects when he perfused frogs with Ringer's solution containing adrenaline. Successive doses of ephedrine produced less and less vasoconstriction, and eventually large doses caused vasodilatation. In this preparation the vasoconstrictor action of ephedrine was probably due entirely to inhibition of amine oxidase, since there was no effect in the absence of adrenaline. The inhibitory effect can be explained on the theory that ephedrine combines with the same receptors in the muscle as adrenaline, but produces no effect when so combined. The receptors thus become blocked up so that adrenaline cannot affect them. Similar explanations have been put forward to account for the antagonistic actions of a number of different pairs of drugs. I think that such a theory was first suggested in 1880 by Ringer and Morshard to explain the antagonism of atropine and pilocarpine on the frog's heart. It is similar to the theory of substrate competition, which I have already discussed. Curtis (1929) put forward this theory to account for the action of large doses of ephedrine in antagonizing adrenaline. He could not explain the diminishing effect of successive doses of ephedrine in this way, because he supposed that ephedrine was acting in the same manner as adrenaline, and it would not seem likely that ephedrine could antagonize itself by keeping itself out, so to speak. The most reasonable explanation now seems to be that ephedrine antagonizes itself by keeping out the adrenaline through which it would otherwise have acted.

### Uses of Ephedrine

Pharmacology can sometimes point the way to therapeutics, but it is often very difficult to predict what the end of the journey will be like. I believe that the first sample of ephedrine to enter University College Hospital did so in 1925—in my pocket. Little was known at that time about ephedrine except that it produced prolonged stimulation of the sympathetic and was active when given by the mouth. Perhaps it should have been possible to foresee most of the clinical applications but a knowledge of these has come gradually and rather erratically. I remember thinking that ephedrine might be of value in Addison's disease. Experience showed that it is not

The oldest clinical use of ephedrine depended on its action on the pupil. If a 6 per cent solution is dropped in the eye the pupil dilates in about 7½ hours, and stays dilated for five to twenty hours. The pupil still reacts to light and accommodation is not affected. Ephedrine has been employed for ophthalmological diagnosis in preference to atropine or homatropine. It is said not to increase the intra-ocular pressure.

The best-known use of ephedrine is probably in the treatment of asthma. It dilates the bronchi and relieves attacks in much the same way as adrenaline, compared with which it is less often effective, but its action lasts longer, and it can be taken by the mouth. I suspect that many people take too much. An eighth of a grain is often enough. It has been found to relieve whooping cough. It has also been used with a certain amount of success in other allergic conditions such as hay fever and urticaria. It is used to prevent, or cure serum sickness. It is having rather a vogue now for local application to the nose where it produces vasoconstriction and dries up secretions. It is of little or no value in vasomotor shock, but it is employed to counteract the fall of blood pressure due to a spinal anaesthetic. Ephedrine has been used successfully in both the prevention and the cure of the attacks of heart-block known as Stokes Adams's syndrome. This is an effect which might have been predicted, because an improvement in conduction in the bundle of His is one of the effects of sympathetic stimulation.

Ephedrine has been widely and successfully used to prevent the pathological sleep of narcolepsy, though it is being replaced for this purpose by its more efficient chemical relative known by the name of benzedrine. The fact that benzedrine produced this effect was discovered suddenly and accidentally, but the history of this use of ephedrine is long and complicated. In 1913 Arritt tested the action of the series of drugs in waking up rabbits which had been anaesthetized with chloral hydrate. He knew that cocaine had a stimulant action on the central nervous system, and found that it would wake up his anaesthetized rabbits. He also knew that cocaine stimulated some parts of the peripheral sympathetic system, and thought that the two effects might be associated. So he tested other sympathomimetic drugs for their power to wake up rabbits. His theory was wrong, because adrenaline had no action so that the two effects were not necessarily associated, but ephedrine woke the rabbits up. Later work has shown that ephedrine has complex effects on the central nervous system which are not yet understood. It has been found to awaken animals anaesthetized with avertin, paraldehyde and evipan. It also restores reflexes and stimulates the respiration, but it seems to have the opposite effect on animals anaesthetized with barbitone or phenobarbitone. Clinically ephedrine has been found to encourage sleep in children and to prevent it in adults. It causes euphoria in some people. The discovery of these facts led to the use of ephedrine in narcolepsy.

The use of ephedrine in myasthenia gravis could not, I think, have been predicted. Its value in this disease was discovered accidentally by Harriett Edgeworth (1930), who was both a scientist and a victim of the disease. She was taking ephedrine for dysmenorrhoea and found it had a very good effect on her myasthenia. This observation was confirmed, but not explained. It has tended to be overshadowed by the marked effect on this disease of physostigmine and its relations. The use of ephedrine in dysmenorrhoea was originally based on the questionable

theory that dysmenorrhoea was due to parasympathetic over-activity. Favourable reports have been published.

Ephedrine is also employed in enuresis. Its effectiveness—if it is indeed effective—might be explained in the same way but it is more likely that the action is on the central nervous system. Perhaps I should add that like so many drugs ephedrine has been recommended as a cure for sea sickness.

The toxic effects ascribed to overdosage are general nervousness and insomnia and tremor vomiting and sweating palpitations urinary retention and skin eruptions. When large doses are given to rabbits over a long period they cause enlargement of the heart with pronounced degenerative changes (Rühl 1929).

The psychological reactions of thirty problem children who received benzedrine sulphate for one week are recorded by C Bradley (*Amer J Psychiat* November 1937 p 577). In fifteen there was spectacular improvement. Many became much less emotional without however losing interest in their surroundings they also experienced a sense of well being. In this group were some children who had previously expressed their irritability in group activities by noisy aggressive and dominating behaviour these became more placid and easy going under the influence of benzedrine. No significant changes were detected in the blood or body weight but in six cases the onset of sleep was delayed for the first night or so. Loss of appetite and nausea were shown by a few children only. The behaviour changes reached their maximum during the second and third hours after the administration of the drug and there was a gradual reversion to the state normal for the particular child during the following six to twelve hours. In all cases the full effects became manifest on the first day of administration continued daily through the week and disappeared as soon as the drug was discontinued. The optimum dose was found to be 20 mg. In eight cases gastro intestinal symptoms were provoked these eight children were given subsequently daily doses of 10 mg for a week, two derived no benefit, suggesting that the lowest dose which they could tolerate was therapeutically ineffective. No relationship was established between the children's ages or weights and their reactions to benzedrine. The author advises that this drug should be further tested experimentally before being recommended for the treatment of behaviour problem children. He suggests that its action might be explained on the lines that it rectifies the impaired control activity which has given rise to disorders of behaviour.

## AMENORRHOEA ITS AETIOLOGY AND TREATMENT\*

BY

T N MacGREGOR, M.D., F.R.C.S. Ed., M.C.O.G.

Assistant Gynaecologist Deaconess Hospital, Edinburgh  
 Lect. Tutor in Clinical Gynaecology, Royal Infirmary  
 Edinburgh. Critic in Research Scholar

The data accruing from the present-day intensive study of sex physiology are at times bewildering and often overwhelming in their complexity. Nevertheless from a conflicting mass of scientific evidence new facts are emerging which are furthering our knowledge of the processes associated with menstrual and reproductive function and new therapeutic agents are gradually being added to the armamentarium of the clinician. These new therapeutic agents have been enthusiastically accepted and applied in the treatment of all gynaecological conditions that might be associated with underlying endocrine disturbances. In some such conditions they are eminently successful—for example in many postmenopausal disorders—but endocrine therapy has not fulfilled the early promise predicted. Disappointing response to treatment however may not be due to faulty or ineffective preparations but rather to their indiscriminate application. Without some knowledge of the therapeutic action of the various sex hormones and their relation to the mechanism of menstrual periodicity therapy must in the main be conjectural. In this paper I am dealing with a small series of seven cases of amenorrhoea most of which have been investigated as fully as present-day methods permit.

## Methods of Investigation

1 *History*.—A full anamnesis is of great importance. Special attention should be directed to the state of previous health and to the occurrence of any unusual circumstances present immediately before or at the time of cessation of menstruation. Frequently a history of change or occupation domestic worry grief or social estrangement is obtained which has an important bearing in regard not only to aetiology but also to prognosis and treatment. Details of previous menstrual rhythm and loss should be elicited. The presence or absence of menorrhagia may also be important as regards prognosis. The presence is rather more favourable than the absence. Information should be obtained as to any increase of weight and its association with the onset of amenorrhoea.

2 *Detailed Examination of the Reproductive Tract*.—Whilst the whole reproductive tract must pass under review the size of the uterus requires special attention as in many cases this gives an approximate index of ovarian function. It is important where possible to examine the endometrium histologically—first, to exclude tuberculosis and secondly to obtain information regarding ovarian activity.

3 *Radiographs of the Sella Turcica*.—Though pathological changes of the sella are rarely found, we may discover in some cases distortion of the sella pointing to gross pituitary disease. Occasionally amenorrhoea is one of the initial features in pituitary lesions and it is on account of the cessation of menstruation that the patient may seek medical advice.

4 *Estimation of the Basal Metabolic Rate*.—This is the only available method of forming an approximate estimation of thyroid function. As the function of the

\* Lecture delivered (by invitation) at the British Postgraduate Medical School, Hammersmith Hospital, London.

thyroid gland is controlled by a specific hormone of the anterior pituitary some knowledge of its activity may provide an index of pituitary function. However, although a hypophysis is functioning in a normal manner in regard to its thyrotropic secretion, this does not necessarily imply that it is also active in respect of its gonad-stimulating hormone.

**5 Determination of Sugar Tolerance**—As pancreatic function is controlled by a specific hormone of the anterior pituitary this test may sometimes be of value as an index of pituitary activity. Occasionally, however, amenorrhoea is the only symptom in early cases of diabetes mellitus, and unless the sugar tolerance is determined the condition may be entirely overlooked until it has reached a more positive phase.

**6 Determination of the Hormone Excretion**—Estimation of the urinary excretion of the gonadotropic and the follicular hormone affords presumptive evidence of anterior pituitary and ovarian function. As these glands are intimately concerned with the control of the menstrual cycle some knowledge of their activity is of the greatest importance.

In the series of cases under review analysis of the total twenty-four-hour output of urine was carried out, according to the technique already described (MacGiegor, 1936) at weekly intervals over a period of one month or longer, and, considered in conjunction with other data, this has in many cases been of value in formulating a basis of treatment. Low values for oestrin excretion show that ovarian function is subnormal, and therefore a reactivating therapy in the form of hypophyseal preparations is indicated.

### Functional Amenorrhoea

The causes of functional amenorrhoea may be classified broadly into (a) psychogenic influences, and (b) general hormonal disturbances.

#### (a) PSYCHOGENIC INFLUENCES

The underlying cause of the endocrine dysfunction is not clear. The onset of amenorrhoea, however, so often follows a mental trauma as to suggest that the motive factor may in some cases be psychogenic. Further, the data obtained from an analysis of the hormone excretion suggest that the hypophysis is primarily influenced by a psychological factor operating either via the higher centres or directly through its autonomic nervous control. The effect of the psychogenic disturbance varies in degree, depending on individual susceptibilities, from amenorrhoea of short duration to a more marked constitutional upset. In the initial stages of this investigation the importance of a possible psychological factor was not realized, and accordingly definite figures regarding its incidence are not available. In a proportion amounting to 60 per cent, however, this factor was present. As illustrating the influence of minor upsets such as environmental and occupational changes on the menstrual cycle, the menstrual histories of thirty-eight nurses may be cited. It was found that during the first year of their training 29 per cent had amenorrhoea varying in duration from one to ten months.

There are thirteen cases in this series in which the outstanding feature was the constitutional disturbance present. They all had in common loss of weight—compared with normal standards for height and age the pro-

### Classification of Material

Investigation carried out on the above lines showed that in twenty out of a total of ninety-seven cases examined the amenorrhoea was due to a recognizable pathology in the pituitary, ovaries or uterus and in a few cases was associated with systemic disease. These will be the subject of a later article. In seventy-seven cases although no obvious pathological condition was observed laboratory findings disclosed a disturbance of function particularly of the ductless glands closely concerned with the menstrual process. These cases are therefore described as functional.

portion of those under weight varied from -15 to -37 per cent—distaste for food, amenorrhoea, and with two exceptions, uterine hypoplasia (see Table). These features are characteristic of anorexia nervosa. Sheldon (1937) lays emphasis on physical aspects of anorexia nervosa which suggest that in some cases there is an underlying hypofunction of the anterior pituitary. He says 'In the chain of events which leads to amenorrhoea the pituitary is involved. While this is undoubtedly true it may be suggested that in all probability there is an underlying psychological cause in these cases and that the pituitary hypofunction is a secondary phenomenon. As, however, many individuals sustain a similar mental shock

without any resulting sequelae it is presumed that in these patients who display the syndrome of anorexia nervosa there is an inherent psychological maladjustment which cannot withstand mental trauma.

#### (b) GENERAL HORMONAL DISTURBANCES

In approximately 40 per cent of the cases no history was obtained of an abnormal psychological stimulus preceding the amenorrhoea; in these it has been presumed that a general hormonal imbalance was the cause of the menstrual disorder. The investigation of these patients showed however that dysfunction of the pituitary was present. Whether this was a primary or a secondary phenomenon it was impossible to ascertain.

#### Treatment of Functional Amenorrhoea

After each case had been investigated it is outlined the resulting data were studied. Those cases exhibiting deviations from the normal were treated appropriately. For example where the basal metabolic rate was low thyroid medication was given; where anaemia was found iron was administered. Such treatment was not followed by a return of menstruation in any one case. Those who were over weight excluding diabetics were put on a strict anti-obesity regime until their weight was within normal limits. With this treatment alone six patients menstruated spontaneously. It is not clear whether the obesity in such cases is due to a temporary slowing of the general metabolic processes consequent on anterior pituitary hypofunction or is directly associated with derangement of the fat regulating centre in the hypothalamus arising from the same nervous factor as is responsible for the amenorrhoea. Whatever the cause of the obesity or its relation to amenorrhoea a suitable regime to counteract it meets with a favourable result in some cases. It is a clinical impression that a strict anti-obesity regime is more efficacious in such cases than thyroid therapy.

The treatment of anorexia nervosa is admittedly difficult. Psychotherapy may be beneficial but the one patient in the series who was treated in this way although improved in general health remained amenorrhoeic. In my opinion improvement of the patient's general health should be the first consideration and as this is difficult to carry out in domiciliary environment a hospital or nursing-home regime is essential. After a satisfactory response has been obtained from treatment along general lines endocrine therapy should be instituted.

Of the thirteen cases of anorexia nervosa one patient has died as a result of her condition. Seven have had an irregular response to treatment in that one or two uterine bleedings have occurred. The following is the history of one of the cases treated.

*Case No. 85*—This patient aged 18 started to menstruate at 13 and her periods were regular 5/28. Her weight at Christmas 1936 was 9 st 7 lb. She had influenza in January 1937 and was operated on during the same month for appendicitis. After operation her weight was 8 st 13 lb. On return to school she became very worried at not being able to keep pace with her companions. She gradually went off food and in February 1937 her periods stopped. She slowly lost weight and there was a complete loss of appetite and an apparent inability to eat. She also had attacks of biliousness. When seen on July 23 1937 her weight was down to 6 st 7½ lb and her blood pressure was 90/70. On examination no physical defect was found. She was an alert girl always on the move. Her condition was diagnosed as one of anorexia nervosa and complete rest in bed in a home was advised. After a few days of this treatment she began to take an interest in food became relaxed and generally felt better. After seventeen days of this negative regime her appetite

became normal and there was a tendency to increase in weight. It was now considered that more rapid improvement might follow if menstruation could be re-established. In deference to the parents' wishes examination of the reproductive tract was not carried out. It was presumed however from the findings obtained in similar cases that there was a certain degree of uterine hypoplasia. On this assumption and despite the knowledge that the hypofunction of the pituitary might be aggravated oestradiol benzoate therapy was instituted. She was given a daily injection of 5 mg of dimenformin for six days and after a few days a further daily injection of 5 mg for seven days—that is a total dose of 65 mg of dimenformin. On September 10 ten days after her last injection a slight show was seen. The patient was given 100 mouse units of antostab (serum gonadotrophic hormone) intramuscularly at three-day to four-day intervals for five injections and after an interval of ten days a further course of five injections, each consisting of 150 M.U. of antostab plus 100 M.U. of phyostab (urine gonadotrophic hormone) over a period of fifteen days. She had a further show on November 10 and a further course of five injections of antostab plus phyostab was instituted. Uterine bleeding ceased. Uterine bleeding followed on December 8 lasting three days. Her weight had increased to 8 st on December 9. She is taking her food well and is now anxious to resume her studies.

#### Endocrine Therapy

##### (a) OVARIAN PREPARATIONS

The role of oestrogenic therapy in the treatment of amenorrhoea is in my opinion a subsidiary one. There are few cases in which it succeeds when given alone. Such therapy is unnecessary if the uterus is of normal size; this indicates that there is enough hormone in the circulation to stimulate full development of the uterine musculature but not an adequate amount for endometrial growth. When the uterus is in a hypoplastic condition oestrogenic therapy is called for in order to promote full uterine growth and increased tonicity so that the organ may be receptive to the stimulation of the normal secretions of the ovaries when these have been reactivated by anterior pituitary preparations. Should it not be possible to measure the uterus after such treatment the production of uterine bleeding it is suggested may be taken as a rough index of full development of the uterine musculature. The other indication for oestrogenic therapy is the finding of an excess of gonadotrophic hormone excretion. In such cases it may be postulated that sustained overstimulation of the ovary resulting primarily from a temporary hyperactivity of the anterior pituitary may result in a condition of ovarian hypofunction or fatigue. Direct inhibition of the pituitary or stimulation of its secretion as a result of oestrogenic therapy permits the ovary to elaborate its own hormones at a normal concentration. In this way oestrogenic therapy may be curative in some cases manifesting an excessive excretion of gonadotrophic hormone. The importance of urinary hormone analysis prior to treatment is obvious.

Before anterior pituitary preparations were available the oestrogens alone or combined with corpus luteum hormone were the form of therapy most favoured. The general scheme of treatment with the oestrogenic hormones was the intramuscular injection of 5 mg of oestradiol benzoate every three to four days or five injections. If no result was obtained at the end of ten days after the last injection similar courses were repeated always with ten to fourteen days in between. Three cases were treated by oestrogenic substances. Twelve of these including a few who had intensive therapy failed to respond to treatment. Sixteen responded irregularly in that uterine bleeding was provoked as a result of the treatment but there was no continuation of a cycle on its

cessation. In two cases exhibiting excessive excretion of gonadotropic hormone menstruation became regular, and in one it has continued regularly for twelve months, the other, however, relapsed after three cycles. Analysis of the urine during the relapse showed that the excretion of gonadotropic hormone had again become excessive. After further treatment, however, there have been two periods.

#### (b) ANTERIOR PITUITARY THERAPY

The preparations available for therapeutic use are the anterior pituitary gland products, the anterior-pituitary-like or chorionic hormone prepared from pregnancy urine, and the gonadotropic hormone prepared from the serum of pregnant mares. The rationale of this form of treatment is ovarian stimulation, but it must be emphasized that it is a substitutive therapy. I believe that a temporary or, in some cases, a sustained anterior pituitary hypofunction resulting from a psychological disturbance may so vitiate the general hormonal balance that the disorganization may be perpetuated after a normal psychological status has been established. The stimulation of the ovary by anterior pituitary preparations permits it to elaborate its own hormones, which, in turn, stimulate the uterus. The restoration of normal ovarian activity promotes an adjustment of the general endocrinal imbalance.

Four cases were treated with anterior pituitary gland extract (gonadotrophon). In three there was no response, whilst in the fourth case uterine bleeding has been produced during the past five months, a course of therapy, however, was given each month during that time. Many cases were treated with anterior pituitary extract containing thyrotropic hormone (ambion) alone or combined with urine gonadotropic hormone (pregnyl), but no continuous response was obtained with this therapy.

The predominant effect produced by the chorionic hormones in the experimental animal is luteinization of follicles. These hormones have been shown to have no effect on the ovaries of monkeys (Johnson 1935). In amenorrhoea, therefore, where ovarian function is presumably subnormal or in abeyance and the secretion of oestrin is at a minimum, there are no ripening follicles capable of being luteinized. Highly luteinized ovaries, with the elaboration of progesterone, would only rarely bring about a secretory phase in the endometrium owing to the absence of the prior action of oestrin. Support was obtained for this view in that curettage in these cases seldom disclosed an endometrium stimulated to such a degree as to be capable of being changed to a secretory phase. Sixteen cases were treated with chorionic or urine gonadotropic hormone with very disappointing results. Only two responded satisfactorily.

#### (c) SERUM GONADOTROPIC HORMONE

This hormone is capable of stimulating ovarian growth and function in monkeys (Engle and Hamburger 1935), and has a gonad-stimulating effect in the hypophysectomized experimental animal. In this respect its biological action is similar to that of the anterior pituitary gland. At the present time, therefore, this preparation seems to be the one which is likely to be most beneficial in cases where ovarian stimulation is required. Engle and Hamburger have shown that it has the same effect on the ovaries of monkeys as the anterior pituitary hormone found in castrate urine. This hormone believed by many to have a follicle stimulating action only has been demonstrated by Frank Salmon and Friedman (1935) and Lipschutz (1935) also to produce luteinization provided a sufficiently high concentration is given. Since there is no conclusive evidence that more than one anterior

pituitary sex hormone is secreted this postulate has been used as the basis for therapy. It is considered that the difference between the hormone present in pregnant serum and that in urine may be due to chemical interactions. In this series of cases, therefore, both hormones have been given together.

The scheme of treatment adopted was as follows. When the uterus was found to be hypoplastic, as indicated by the length of the utero-cervical canal, oestradiol benzoate therapy was administered until the uterus was fully developed. If the uterus was of normal size initially, this preliminary treatment was omitted. Thereafter 100 M U of serum gonadotropic hormone and 100 M U of urine gonadotropic hormone were given intramuscularly combined as one injection every three to four days for five injections. If no uterine reaction resulted after an interval of ten to fourteen days a further five injections were given as previously, and again after an interval of ten to fourteen days another five injections were given. It is advisable, if there is no response to three courses of injections, to defer further treatment for a period of from two to three months. In a few cases response to the first or second course of therapy was immediately followed by a further course of injections in order to supplement pituitary function and cause full reactivation of the ovaries.

Thirty cases were treated in this way with serum and urine gonadotropic hormones. Of these, ten responded satisfactorily to therapy. In three cases, however, after several months of regular menstruation a period was missed, a further course of serum plus urine gonadotropic hormone was then given resulting in a return of the normal cycle. Twelve responded irregularly in that one or two periods occurred after treatment. Eight failed to respond after one or more courses of therapy. Included in the irregular responses are a number of cases in which treatment has only recently been instituted, and it is possible that several of these may continue to menstruate normally.

The following is a resume of the history and treatment of three of the patients in this group treated by serum and urine gonadotropic hormone.

*Case No. 80*—This patient aged 26 had never menstruated. Her basal metabolic rate was +19 per cent. Blood sugar tolerance: fasting blood sugar 123 mg per 100 ccm at half hourly intervals after 50 grammes of glucose, 180, 140, 125 mg per 100 ccm. The utero-cervical canal was 24 inches in length. The endometrium was scanty and not sufficient for histological examination. The sella turcica was normal. With regard to analysis for hormones, the twenty-four-hour output of urine was examined for the gonadotropic hormone and oestrin on five consecutive occasions at weekly intervals and 40 ccm of blood were also tested for oestrin on four consecutive occasions at weekly intervals. No oestrin was found in the blood by the methods used. The urine gonadotropic hormone on every occasion was negative. The amount of oestrin excreted in the twenty-four hour output of urine was: (1) 19–36 M U, (2) 10–20 M U, (3) less than 11 M U, (4) 22–44 M U, (5) 22–44 M U. On account of the increased metabolic rate treatment with Lugol's iodine was given until the basal metabolic rate was within normal limits. Thereafter hormone preparations were administered over a period of fourteen months in various courses of therapy. The patient was given a total dosage of 16,000 R U of pregnyl, 145 gonadotropic units of ambion and 126 mg of dimenformon. As a result, several uterine bleedings occurred at irregular intervals but there was no continuation of menstruation on cessation of this treatment. The patient was then given 10 courses of 200 M U of serum gonadotropic hormone plus 200 M U of urine gonadotropic hormone combined as one injection at three day to four day intervals, ten days

intervening between each course making up a total of twelve injections. As a result of this therapy the patient had five uterine bleedings at regular monthly intervals. The rhythm was not maintained however and a further course of five injections of serum gonadotropic hormone plus urine gonadotropic hormone was given in May 1937. Since this last course of treatment menstruation has continued regularly at monthly intervals.

**Case No. 65**—This patient a girl aged 17 had never menstruated. Her twin sister menstruated at 14 and has regular periods. On investigation her weight was 7 st 12 lb and her height 5 ft 5 in. Secondary sex characteristics were normal. The basal metabolic rate was -10 per cent. The sella turcica was smaller than normal. Blood sugar tolerance, fasting sugar 87 mg per 100 ccm, at half hourly intervals after 50 grammes of glucose 180 150 120 89 mg per 100 ccm. The external genitals were normal, the cervix healthy and the uterus in good position, the utero-cervical canal measured 24 inches by the sound. The endometrium was so scanty as to be insufficient for examination. The urine was examined for hormone content on two occasions. Urine gonadotropic hormone was negative and urine oestrin less than 10 MU per twenty-four hour output. The patient was treated with Collip's maturity factor over a period of two months without effect. In October 1936 a course of therapy with 200 MU of serum gonadotropic hormone combined with 200 MU of urine gonadotropic hormone was given at three-day to four-day intervals for five injections. There was no result from this course of treatment and it was repeated in November 1936. Ten days after the last injection uterine bleeding occurred for three days, since then menstruation has been regular every twenty-eight days—that is over a period of thirteen months.

**Case No. 35**—This patient a woman aged 24 first came under observation in August 1933. Menstruation began at 15 and had been regular (4/28) until January 1935. Her father died in November 1932. Before any investigation was carried out the patient was put on progynon by injection and drages orally and between August 21 and November 22 1933 71 300 MU of progynon were injected and 7 800 MU given by mouth. Uterine bleeding started on December 3 and lasted five days. A further total course of 20 000 MU was then given by injection and 1 650 MU by mouth in the form of progynon. A uterine bleeding occurred from January 3 to 4 1934. Thereafter another course of 40 000 MU of progynon oleosum given by injection was followed by uterine bleeding on February 25. She then had by injection 80 000 MU progynon oleosum and 120 000 MU oestrogen without effect. The patient was admitted to hospital for investigation. Her weight was 7 st 10½ lb and her height 5 ft 4 in. The basal metabolic rate was -7 per cent. The sella turcica was normal and x-ray examination of the chest proved negative. Blood sugar tolerance, fasting sugar 100 mg per 100 ccm, at half hourly intervals after 50 grammes of glucose 150 126 100 98 mg per 100 ccm. Fields of vision were normal. The utero-cervical canal measured 24 inches, the endometrium was very scanty. The twenty-four hour output of urine was examined for hormones on five occasions at weekly intervals. No gonadotropic hormone or oestrin was demonstrated in the urine but a positive blood oestrin was once obtained.

Between November 18 1934 and May 20 1936 the patient had divided in various courses of therapy 95 mg of dimenarton 9 100 RU of pregnol and 90 gonadotropic units of atbinon in conjunction with 1 800 RU pregnol. During that time the patient saw traces of blood on five occasions. The last bleeding was on March 22 1936. From May 31 to August 25 1936 she was given two courses of serum gonadotropic hormone along with urine gonadotropic hormone. The total amounts of the two courses were 2 000 MU of each preparation. Menstruation started on August 19 the bleeding lasting four days, since then—that is during sixteen months—it has been regular 4-5/28-day type.

It is not likely that menstruation will proceed spontaneously in every case of amenorrhoea responding to

this therapy cognizance must be taken of the motive factor producing the amenorrhoea. It is however probable that menstruation will follow regularly if by periodic supplementing of the anterior pituitary gonadotropic hormone when it is necessary the menses can be kept going long enough. It is not improbable that the dosage of the gonadotropic hormones given in this series was inadequate in many cases but the amounts available at the present time preclude the administration of a much higher dosage.

### Spontaneous Onset of Menstruation

It is difficult to assess the results from any one line of treatment in amenorrhoea as the possibility of the spontaneous onset of menstruation must always be considered. This applies particularly to indiscriminate treatment without prior investigation. Sometimes from an analysis of the urine for hormone content carried out at weekly intervals it can be predicted that menstruation is likely to ensue spontaneously.

In eleven out of seventy-seven cases of functional amenorrhoea menstruation recommenced spontaneously. The period of amenorrhoea varied the longest period of secondary amenorrhoea being five years whilst one patient with primary amenorrhoea started menstruating at the age of 25. This latter case is of interest in that treatment had been instituted over a period of six months and during that time in various courses of therapy the patient had had a total dosage of +600 R U of pregnol 200 mg of dimenarton and 45 mg of progestin. One of these courses was carried out on the lines indicated by Kautmann (1934). No uterine bleeding was produced as a result of the treatment. It must be added that marriage was advised when that question arose with this patient, and after eleven months of conjugal life menstruation ensued. This is the only case of primary amenorrhoea in the series which has menstruated spontaneously.

### Discussion

The factor or factors responsible for the cessation of menstrual rhythm are rarely apparent. It is therefore necessary that every avenue of approach in the investigation of each case be explored in an attempt to elucidate the underlying cause or causes. An investigation such as suggested reveals in some cases a pathological cause of the amenorrhoea but in the majority of cases only disturbances of function are found. Further the investigation is of value in that it often yields presumptive evidence of the degree and nature of the disorder. Rational therapy formulated on this basis is obviously more likely to meet with success than that which is largely empirical.

It has been suggested that the aetiological factor in the majority of cases of functional amenorrhoea is a psychological one, yet in many cases it is undoubtedly not only a suggestion but a true statement of fact. Just as an abnormal psychological stimulus may result in amenorrhoea so also may a similar factor result in a return of menstruation in an amenorrhoeic patient. This may explain why in some cases menstruation recommences spontaneously after months or years of amenorrhoea.

Although in a few cases of amenorrhoea the oesrogenic are of value in many they are contraindicated as they may produce a further inhibition of an already under-functioning hypophysis. The results obtained in the present series and those of many other investigators indicate that the chorionic hormones *per se* have for the reasons already stated very little place in the treatment of amenorrhoea. Until reliable anterior pituitary gland

preparations are available, when a true substitutive therapy can be carried out, the most hopeful preparation seems to be the serum gonadotropic hormone alone or combined with the urinary gonadotropic hormone.

No differentiation has been made between primary and secondary amenorrhoea as it has been found that when congenital defects are excluded the findings are comparable in both types, and therefore the treatment is similar. The prognosis is just as favourable in primary as in secondary amenorrhoea.

### Summary

1 The investigation required in a case of amenorrhoea is detailed, and some consideration is given to the value of each procedure.

2 The primary and secondary factors responsible for the inhibition of menstruation are discussed.

3 The results of treatment based on the investigation findings are presented.

My thanks are first of all due to the members of the honorary gynaecological staff of the Royal Infirmary, Edinburgh for permission to investigate and treat cases under their care. I also most cordially thank Dr A. N. Macbeth of Organon Laboratories, Dr H. Neumann of Schering Ltd., Dr T. A. Lloyd Davies of Boots Pure Drug Co. and Messrs. Prunes and Byrne Ltd. for the generous way in which they have placed their preparations at my disposal. I also express my appreciation and thanks to Glaxo Laboratories for making available to me large amounts of anterior pituitary preparations.

The expenses of this investigation were partly defrayed by a grant from the Medical Research Council.

D. Whyte and R. O'Regan (*N. Zealand med. J.*, December, 1937, p. 381) refer to a previous paper published in February 1937 in which they stated that the treatment of complete prolapse of the rectum by Gabriel's injection technique was "safe, painless and effective." They now wish to qualify this statement, as a case has been seen in which the patient's life was in serious danger for some weeks from sloughing of the rectal wall and secondary haemorrhage, although the final result was satisfactory. The patient, a man of 55, was suffering from intractable prolapse of the rectum with continued mucous discharge. Seven submucous injections were given each of 2 c.c. of 5 per cent carbolic acid in almond oil, and three perirectal injections of saline solution. Vomiting and headache persisted for a week, and on the eleventh day after operation a sudden copious haemorrhage from the rectum occurred. Examination under anaesthesia was carried out, and a large sloughing area was found on the posterior wall of the rectum extending into the pararectal tissues the sacrum being palpable through a mass of blood clot. An acriflavine gauze pack was inserted and was replaced two days later by a small flavine vaseline pack. Nineteen days after the original operation a left inguinal colostomy was done. Six blood transfusions had been given during this period and repacking had been carried out several times on account of bleeding. At the end of two and a half months proctoscopy showed the rectum to be healed and firmly fixed in the sacral hollow, and at the end of a further month the colostomy was closed and the patient made a good recovery.

## RATE OF SEDIMENTATION OF RED BLOOD CELLS AS A CLINICAL TEST IN GENERAL PRACTICE

BY

E. SCOTT, B.A., D.M., B.Ch.

This investigation was undertaken two years ago to determine the value of the blood sedimentation rate (BSR) as a test for the general practitioner. From my material I have chosen the experiments which are most likely to be of use. For the test to be practical it must conform to certain conditions. It must be quick, easy of application, and independent of elaborate apparatus. These conditions are satisfied. The blood can be collected and the tube filled in the time it would take to spread a blood film, and the reading, which takes place an hour later, can be jotted down by any educated person. The work has been done in three places—Ashford Hospital, my surgery, and the patient's home. As regards the last mentioned, to avoid the dangers of transport with a filled tube it is a good plan to leave the tube to be read by the patient at the required time or marked with a strip of stamp paper. Attention to minute differences in end results is undesirable and may be misleading. The BSR is altered in a variety of pathological conditions that affect the body as a whole. It is thus, within limits, an indication of the existence of organic disease, particularly of an inflammatory nature, and a guide in the assessment of recovery. In theory it runs parallel to the temperature chart, but it covers a wider field, is slower to rise and decline, and can indicate infection in the absence of pyrexia. It affords a closer comparison with the Arneth count. It is the extent and scope of the test which constitute its strength and weakness and render its investigation difficult. The test has become a routine one in hospital practice in many parts of the Continent, particularly Germany, Scandinavia, and Switzerland. It is rapidly becoming popular in England, where it is used as a standard control in the treatment of tuberculosis and chronic rheumatism. Individual readings are not very instructive. I have, in consequence, endeavoured to gain information by choosing cases of known disease and compiling charts with BSR readings as far as possible from inception to cure. In most cases these are correlated with temperature readings.

### Technique

There is a somewhat wide choice of tubes, but I have found that Linzemeier's answers all requirements. This tube is marked at the level reached by 1 c.c. of fluid, and is graduated in millimetres downwards to 24. The reading is particularly easy, and it is noteworthy that if these graduations are extended they divide the c.c. into 48, so that figure 1 on Linzemeier's tube represents roughly a BSR of 2 per cent. This affords a useful method of comparison with other apparatus. With a hypodermic syringe and needle a solution of 3.8 per cent sodium citrate is drawn to the 0.2 c.c. mark and blood is collected from a vein until the 1 c.c. point is reached. The piston is then withdrawn slightly and the syringe contents are thoroughly mixed by repeated inversion. The citrated blood is injected into the sedimentation tube up to the top mark (1 c.c.). The tube is placed vertically in a stand and the height of the supernatant clear fluid read off in an hour's time. These tubes are made by Hawksley and Sons, and I have obtained them from

Allen and Hanbury's who also supply the sodium citrate solution in convenient rubber capped bottles. It is well to run sterile water (not alcohol) through the syringe and needle and to cleanse the tube with sterile water immediately before use. There is usually slight misadjustment to the 1 cm mark owing to the presence of bubbles in the citrated blood but the margin of error is seldom greater than 1 and is too small to be of clinical importance. The arbitrary limit where the BSR becomes pathological has been suggested by Dr T C Hunt to be at the 10 mark and I have adopted this as a working criterion of the normal. It must be understood that BSR = 10 like 98.4 F on the temperature chart represents a maximum and not an average or ideal

to be more stable in the male (Note the rise to 9 on March 18 which is analysed more fully in Chart B). No 2 is very unstable at the beginning a period of malaise followed by the rise to 15 on June 25 culminated in a violent bilious attack—an unexpected occurrence with no apparent explanation. The rises to 9 on October 9 and to 10 on December 18 were the accompaniments of a severe head cold. No 3 presents many difficulties. The BSR was very high in the early stages. At this time the individual was greatly below weight (7 st 7 lb) but this began to go up in the autumn reaching 8 st 4 lb in October and thereafter remaining steady. This was an index of a general improvement in health which is probably reflected in the lower level and increased stability of

CHART A (1, 2, and 3)

The temperature to which the tube is exposed has been stated to exercise a disturbing factor on the end result. A few simple experiments have convinced me that this factor can be disregarded in practice. The tubes should be stood in an ordinary room. So long as the direct rays of the sun or the immediate vicinity of a fire are avoided I do not anticipate any difficulty from variations in temperature. Anaemia can of course profoundly affect the result. It is sufficient to say here that small degrees involving a haemoglobin content of not less than 80 per cent are not of material importance.

#### The BSR in Normal Health and its Relation to Minor Disturbances

With this particular technique 10 has been generally adopted as the maximum BSR reading in normal health. Making a series of tests in persons apparently in normal health I found the average reading to be 4 in men and 6 in women. Most observers agree that the BSR tends to be at a higher level in women than in men. Another interesting find is that if the BSR of the same individual is taken at different times a variation of two, three or even four in the reading is frequently encountered for no obvious cause and corresponding to no obvious deviation from health. In order to investigate this more thoroughly charts were instituted of three individuals—myself (Chart A No. 1) and two nursing sisters (Chart A Nos. 2 and 3). Readings were taken at weekly intervals throughout the year and omissions reduced to a minimum. Minor maladies not sufficient to incapacitate such as colds are indicated as far as possible.

If we attempt to analyse these three charts separately we note the comparative stability of No. 1. It is probable that as in most clinical tests of this sort the BSR tends

to be more stable in the male (Note the disturbance caused by a cold on December 18).

The consideration of Charts A 1, 2, and 3 leads to the conclusion that each individual has an optimum BSR and that moderate deviations indicate minor maladies. In the case of No. 1 the optimum is 2; that of No. 2 is 6

CHART B

and that of No. 3 is 9. Consequently a BSR of 9 in the case of No. 1 would indicate minor illness whereas the same reading in the case of No. 2 would be compatible with complete well being. The 10 mark is no in every instance a true maximum of the normal but it affords a fairly accurate working criterion. Chart B is an analysis of my own BSR during a severe influenza cold in March. Note the fairly rapid rise and the slow decline, the latter lagging after the clinical symptoms had cleared up.

#### The BSR in Pregnancy

Fahraeus was the first to point out that the BSR constantly raised during pregnancy, the only physiological condition in which this phenomenon has been observed

The change, however, does not take place until the later months, and the test is valueless in the diagnosis of pregnancy during the early stages. Chart C was that of a primipara, and began at the tenth week of gestation. For Chart D I am indebted to Dr J A Moore Hall. The BSR readings during pregnancy have been charted, and the matter is pursued to its conclusion where the BSR returns to normal in the fourth week of the puerperium.

### BSR in Infections

In the role of the BSR in acute and chronic infection lies its main claim to merit as a clinical guide. It can be discussed under three headings: (1) localized, (2) pulmonary, (3) general. The last two have been, and are still being, the subject of extensive investigations by many

discomfort the patient made a normal recovery. The BSR was only 6 on the day following the onset of the illness and on the fourth day reached 18 where it remained for a few days before starting to decline.

**Case 2 (Chart F)**—A healthy man aged 49 was admitted to hospital for inguinal hernia. Operation was performed and progress was satisfactory until the seventh day, when severe pain was felt in the right side with rise of temperature, apparently from pulmonary congestion or a small infarct. Pain lasted for a few days after the temperature had fallen. Note the slow but steady fall of the sedimentation rate and the (presumably) steep rise. The BSR apparently started at normal. It reached 18 on the third day after the onset of symptoms and its peak (28) on the fourth day, which was two days after the pyrexia had declined and the patient's symptoms had nearly cleared up. Subsequently its fall was uneventful.

CHART C—Readings during pregnancy

CHART D—Readings during pregnancy

CHART E (Case 1)

CHART F (Case 2)

CHART G (Case 3)

workers throughout the world, particularly as regards pulmonary tuberculosis in the one case and rheumatoid arthritis in the other. I accordingly devote myself to the phenomena observed in localized infection.

The characteristic of the BSR curve in the case of an acute infection which ends in recovery is a comparatively steep rise and a slow gradual descent. Though the rise is steep it is slow compared with temperature or pulse-rate variations which, in the case of fulminating disease can show extreme disturbance within a few hours. The BSR is unlikely to present much change in the first forty-eight hours and is hardly likely to reach its peak before the fourth day—often an appreciable time after the maximum pyrexia. This is demonstrated in Charts E, F and G.

**Case 1 (Chart E)**—In this case that of a man aged 37, operation was performed for acute appendicitis on November 4, 1934, the second day of the illness which had supervened on a subacute condition lasting three weeks. The appendix was full of pus. Drainage was not done. After a few days

**Case 3 (Chart G)**—The patient a man of 50, was pale, thin, and anxious. Appendicectomy for chronic abdominal pain was performed on October 25, 1934. Recovery was uneventful until October 29, when he complained of acute pain in the left side. The temperature rose steeply, and he developed the physical signs of pleurisy in the left base. Recovery took place and the temperature subsided by November 7, a few days after which he was allowed to get up. Radiographs taken on November 12 revealed a patch, indefinite in outline at the left base and a small quantity of pleural fluid. The next day the fluid had disappeared but the patch was still distinctly visible in the film. The patient was discharged well on November 17. His BSR was 12 on the first day of the pleurisy, when his pyrexia was at its peak at 102 F. The BSR reached 24 three days later and remained there for four days, starting a steady decline four days after the main febrile disturbance had subsided.

This methodical use of the BSR limits its value in the diagnosis of acute disease, and reserves its main field of usefulness for chronic infection. For instance, it is valueless as a guide in acute appendicitis, where operation

thoroughly cleared pus being found. Convalescence was uneventful and she was discharged on May 15 with the wound and the tympanum healed and hearing nearly restored to normal. Complete recovery ensued, and the patient had no complaints to make when last seen on September 25.

### Summary

1 A simple method is described in which Linzemeier's tube is employed.

2 The figure 10 is selected as the usual maximum reading attained in health.

3 A chart method is employed. By taking weekly readings throughout the year it is shown (a) that the BSR varies in health within moderately wide limits, (b) that each individual has an optimum reading, (c) that moderate deviations from this can usually be attributed to minor ailments.

4 During pregnancy the BSR is undisturbed until about the fourth month, when a steady rise takes place till term.

5 General principles are deduced from the behaviour of the BSR in local infection. The rise of the BSR to an appreciable degree takes about three days. Its decline is comparatively slow, and is (a) continuous and satisfactory, (b) interrupted, due to complications, or (c) incomplete and unsatisfactory. Cases should be followed up until the BSR returns to normal.

I owe my thanks to Dr T. C. Hunt, who first aroused my interest in the subject and to Professor J. R. Fraser for suggestions and criticism.

Towards the expense of this research a grant was made by the British Medical Association.

## ASCORBIC ACID IN BRONCHIAL ASTHMA

### REPORT OF A THERAPEUTIC TRIAL ON TWENTY-FIVE CASES

BY

H. B. HUNT, M.D.

There is a certain amount of evidence that ascorbic acid may play a part in allergic conditions in general and asthma in particular which, although suggestive, is difficult to correlate exactly, and is perhaps best classified in three groups as follows.

#### Theoretical Considerations

1 Hypersensitivity to foreign proteins results after adrenalectomy in dogs (Simpson, 1937). In asthma a condition of protein hypersensitivity also exists, and hypoplasia of the adrenal glands has been noted in asthmatics coming to necropsy (Adam 1931, Waldbott, 1933-4). An eosinophilia is not uncommon in either asthma or Addison's disease. At least one case has been recorded of the association of these two conditions (Wilkinson, 1937).

2 Adrenaline, the most potent anti-allergic remedy yet known, is a secretion of the adrenal medulla. The fact that cortical extracts have been employed in asthma without any marked success (Cohen and Rudolph, 1934-5, Wilmer and Miller 1936) tends to show that if the suprarenal glands are affected in this condition then the medulla rather than the cortex is involved.

3 Ascorbic acid is normally present in the adrenals. Indeed it was from this source that Szent-Györgyi originally isolated vitamin C.

From these disjointed observations it appears probable that (1) asthma or allergy may be associated with adrenal hypofunction, (2) the medulla is chiefly at fault, (3) some especial relation exists between ascorbic acid and the adrenals. Dr L. J. Harris has suggested (in a personal communication) that as, in the light of recent observations, one of the functions of ascorbic acid appears to be to prevent the oxidation of adrenaline, it may be possible, by giving suitable doses, to conserve sufficient adrenaline to prevent the occurrence of asthmatic symptoms.

#### Vitamin C in Anaphylaxis and Allergy

Claims have been made that ascorbic acid will protect guinea-pigs against anaphylaxis (Hochwald, 1935, Salomonica, 1936), and in human beings will diminish the cutaneous reactions to tuberculin, in positive reactors when given intravenously (Heise *et al.* 1937). Hochwald (1936) has employed ascorbic acid in cases of bronchial asthma, and found it of some value in preventing symptoms when given regularly, or aborting symptoms when injected intravenously in massive doses (500 to 1,500 mg). Epstein (1936), while unable to confirm the work of Hochwald when he used ascorbic acid in either asthma or hay fever, did find that it was distinctly valuable in the treatment of asthma if employed in conjunction with injections of gold salts.

#### Investigations

In view of what has been said above there is reason to expect that ascorbic acid may prove useful in the treatment of bronchial asthma. It is not suggested that asthma is a deficiency disease or even that the majority of asthmatics suffer from a subclinical C avitaminosis. Ascorbic acid was given to exert any anti-allergic properties which it may possess rather than to correct a specific deficiency. As all of the cases were out-patients it was not practicable to employ the usual laboratory procedure of estimating any possible avitaminosis. However, among the whole of the patients attending the asthma clinic of the Birmingham General Hospital during the last year I detected only one who showed any clinical signs of vitamin C deficiency. In this case the symptoms—bleeding of the gums and lassitude—were very mild, and cleared up after suitable treatment with ascorbic acid.

*Clinical Material*—Twenty-five patients were investigated—sixteen females and nine males, five of them were children. Other allergic symptoms were present in seven teen cases, and chronic bronchitis in nine. Thus, although small, the series was fairly representative.

#### Dosage and Method of Administration

The ascorbic acid was dispensed in tablets of 50 mg (the synthetic preparation of Roche Products Ltd, redoxon, was employed throughout), two of these being given for each day, one to be taken in the morning and one at night. Each patient received one or two weeks' supply of tablets when attending the clinic. The course was designed to last for eight consecutive weeks, but as attendances were not as regular as could be desired all the patients did not complete eight weeks' treatment and of those who did not every one covered the course in eight consecutive weeks. During this treatment no medicine or injections such as vaccines were given apart from antispasmodics—for example ephedrine or "felfol" powders—or medicine for a troublesome cough. Five patients (quite apart from the group of twenty-five mentioned above) seen when symptoms were present were

given massive doses of ascorbic acid by injection. One of them received 500 mg intramuscularly, another 800 mg intravenously and the remaining three 500 mg by the same route.

### Results

In reviewing the twenty five cases after several weeks treatment by oral medication with 100 mg of ascorbic acid daily no evidence could be found of any marked improvement in the amount of wheezing, the incidence of attacks or the general condition. None of the five patients who received injections of ascorbic acid in doses of 500 mg or over experienced any relief in their symptoms after a period of twenty to thirty minutes and the amount of adrenaline subsequently required to relieve the spasm was in no way diminished. Thus it was impossible to confirm the statement of Hochwald (1936) that asthmatic symptoms could be relieved by large intravenous injections of ascorbic acid. It may be mentioned that in these five cases symptoms were severe in two instances and slighter in three.

### Conclusions

The investigations described above have not shown ascorbic acid to be of any value in the treatment of bronchial asthma when given in comparatively large doses either by injection or by mouth.

I wish to thank Professor W. H. Wynn for the facilities he offered me in the investigation and also Roche Products Ltd for the supplies of redoxon which they kindly placed at my disposal.

R. Benda (*Prag med Z* January 25 1938 p. 67) does not agree that a retroverted uterus discovered during a routine examination and producing no symptoms should be left untreated. He recommends replacement and insertion of a pessary in all cases. Operative treatment is indicated if after one year's conservative treatment the uterus still becomes displaced after removal of the pessary. Replacement of a gravid retroflexed uterus should only be undertaken in hospital. Although spontaneous replacement may take place and although it may be aided by lying in the prone position it must not be left to chance. When retroversion is due to pelvic peritonitis conservative treatment of the pelvic inflammation is indicated. The insertion of a ring pessary in the treatment of uterine prolapse is only of value when the levatores ani are still intact. It is valueless when the neck of the cervix is elongated and when cystocele or rectocele is present. Of the various operative procedures Benda advises Wertheim-Schauta's method of interposition of the uterus between the vagina and bladder or Halban's fixation of the uterus to the bladder. He attacks anterior and posterior colporrhaphy as an operation attended by an appalling proportion of relapses. Measures for the prevention of uterine prolapse include careful forceps deliveries, more frequent use of episiotomies and exercises in the puerperium. Benda advocates that women should be encouraged to get up five days after a normal confinement but they should not be allowed to do their ordinary work for some time afterwards.

## THE FEMALE CLIMACTERIC AND THE MENOPAUSE

By

H. R. DONALD, M.A., B.M., M.R.C.P.

Honorary Physician Manchester Northern Hospital, Streeter Memorial Hospital and Royal Eye Hospital  
Visiting Physician Crumpsall Hospital

The recent advances made in the physiology of the sex hormones have tended to stimulate rather than to satisfy our curiosity. The shafts of light that have been shed on a few isolated points have by contrast served merely to accentuate the darkness of surrounding ignorance. This is particularly true of the existing knowledge of the female climacteric. The common employment of the terms menopause and climacteric as though they were synonymous advertises the looseness of present conceptions for although both these conditions possess certain similar features there is no possible justification for regarding them as identical. Some of this confusion may be due to the tendency to make deductions from the similarity of the symptoms of the artificial and of the physiological menopause. Such argument by analogy is always risky as in the case of the experimental diabetes of pancreatotomy and its supposed clinical counterpart and in view of the unknown causation of the physiological menopause any inferences should be drawn with extreme caution. Since a clear differentiation between the menopause and the climacteric is becoming increasingly important the two subjects are here reviewed from both the theoretical and the clinical standpoint.

### The Menopause

The use of the term menopause should be restricted to its literal meaning of the cessation of the menstrual life. It should also imply the termination of the menstrual life. The cause of this permanent amenorrhoea is not known but it is commonly accompanied by two principal endocrine changes. First there is a relative diminution in circulating oestrogens which are almost or completely absent from the blood stream three years after the cessation of the menses in probably a less than 10 per cent of women. It is doubtful however if the menopause is due directly or solely to a decline in the ovarian secretion of full endometrial hyperplasia which may be regarded as a specific oestrogenic function may persist for many years after the establishment of amenorrhoea. Its occurrence has been variously reported in forty out of 130 and thirty out of 130 postmenopausal subjects (Noyl and Taylor 1936). The site of formation of these oestrogens is not known but some at least may originate in the ovary. In the second place there is an increased content of prolactin in both the pituitary gland and the urine and the significance of even this finding is not appreciated. The increased content of prolactin in the pituitary is probably more characteristic of a resting than of a secreting state and it may be of interest to quote the work of Engelhart and Häusler (1936-7) who reactivated the senile ovaries of rats by the implantation of pituitary tissue.

### The Climacteric

The term climacteric is derived from the Greek meaning a rung of a ladder and originally was used to describe certain critical epochs in the life of both men and women at which the body was considered to undergo radical changes. These epochs were supposed to recur at intervals of nine years from the commencement being a adolescence and at the sex period years the

latter being referred to as the "grand climacteric" The term may therefore be used to signify certain changes in function, and to a less extent in structure, which take place at or after middle age These changes lack any uniformity and show great variation in severity The most distinctive mental changes are a progressive introversion of the mind, with depression, inertia, and insomnia, while the normal physiology of the body is subject to innumerable disturbances, the majority of which are characterized by transient or persistent sympathetic discharge (Donald, 1937) common among these latter symptoms are headache, dizziness, various rheumatic affections, and swelling of the extremities or face

In the past no investigator has drawn any practical distinction between the menopause and the climacteric and hence no attempt has been made to establish any endocrine relation or difference between these two conditions From the clinical view-point there can be but little doubt that involutionary changes affect glands other than the ovaries A mild degree of myxoedema is considerably more common than states of true hyperthyroidism, the occasional occurrence of which may perhaps be due to the trophic influence on the thyroid gland of a hypertonic sympathetic nervous system Similarly, the majority of cases of diabetes mellitus which originate at the climacteric would appear to be due to a depression of insular activity, and only a small percentage of cases may be attributed mainly to excessive glycolysis from sympathetic discharge I have seen several cases the symptoms of which bore a striking resemblance to Addison's disease, even to the characteristic pigmentation and fall in blood chlorides It would therefore seem likely that these multiple glandular disturbances may possess some common origin, which for reasons previously mentioned may well be a reduced secretion of the anterior pituitary

It will thus be seen that the climacteric differs from the menopause in being a general rather than a local disturbance, and in being a chronic immeasurable clinical state rather than a clear-cut observable symptom

#### Relation between Menopause and Climacteric

In the past it has been assumed that the menopause initiated the climacteric and that the two conditions were clinically inseparable This conception is open to considerable criticism and doubt Since the principal symptoms of the climacteric are to a large extent non-specific in nature and essentially nervous in origin, their time of onset severity, and chronicity may be regarded as the resultant of at least two intrinsic forces (1) the fundamental constitution of the individual, in which I include the basic endocrine pattern and its consequent influence upon the tone and equilibrium of the autonomic nervous system, and (2) the individual degree of endocrine change which occurs at the climacteric In general the more unstable a nervous system is the smaller are the degrees of endocrine change which are capable of disturbing it Now since this constitutional factor varies so widely in different individuals considerable variation in the onset and severity of climacteric symptoms might be expected, even supposing that the rate and degree of endocrine involution were constant In point of fact, however, much evidence has recently accumulated to suggest that these endocrine changes also are subject to great individual variation

Although in many women oestrogenic substances are absent from the blood and urine three years after the menopause, in many others this reduction is extremely

gradual, for these substances have been found to persist in considerable quantity in both the circulation and the urine for twenty years or more after the menopause (Robson *et al* 1934, Frank, 1934, Frank, Goldberger, and Spiegan, 1934, Frank Goldberger, and Salmon, 1936) A further indication of this persistent oestrogenic secretion may possibly be given by some observations which I have made on the amounts of oestrone and oestradiol that are effective in producing proliferative bleeding in the post-menopausal subject The work of Kaufmann and others has demonstrated that approximately 25 mgm of dihydroxoestrin injected intramuscularly are required to produce proliferation of the endometrium in the castrated subject In the treatment of the climacteric by oestrogenic compounds, however, ten out of 120 patients have reported the occurrence of uterine haemorrhage after very much smaller amounts Details of these cases are summarized in the accompanying table

Case No	Age	Years past Menopause	Duration of Treatment in Weeks Prior to Haemorrhage	Weekly Replacement of Oestrin in Mg	Total Replacement in Mg
1	69	18	13	1 B 2 O	13 B 26 O
2	63	17	5	6 B 3 O	31 B 5 O
3	63	11	4	1 B, 2 O	4 B 8 O
4	58	18	4	2 B, 2 O	8 B 8 O
5	57	10	6	2 B 2 O	12 B 12 O
6	56	5	9	2 B, 2 O	18 B 18 O
7	54	4	24	1 B 2 O	24 B 48 O
8	50	2	20	2 B 2 O	40 B 40 O
9	50	1	6	2 B 2 O	12 B 12 O
10	48	1	5	2 B 2 O	10 B 10 O

B Dihydroxoestrin benzoate given intramuscularly O = Oestrone given by mouth

Cases 3, 6 and 7 were curetted and typical endometrial proliferation was found Case 2 had a recurrence of haemorrhage after six weeks of further treatment by 0.6 mg oestrone daily by mouth

The figures show that there is a marked difference in response between the castrate and the post-menopausal subject\* From these considerations two conclusions may justifiably be drawn

1 The severity of climacteric symptoms need not be in proportion to the degree of endocrine change This has already been pointed out by Salmon and Frank (1936) who found that such symptoms could not be correlated either with the amount of circulating oestrogens or with urinary prolactin and yet these symptoms could be relieved by the adequate administration of oestrin

2 Great individual variation may be expected not only in the severity and chronicity of the climacteric but also, and more particularly, in its time of onset

From the theoretical side alone, therefore there is reason to suspect that the menopause and the climacteric may not always possess a close temporal relation

#### Practical Considerations

How are these theoretical considerations borne out in practice? In probably 80 to 90 per cent of women the menopause is closely related to the onset of climacteric symptoms These symptoms usually coincide with the cessation of the menses, but may precede or follow the establishment of amenorrhoea by a few years While this close association of the menopause to the climacteric

\* One apparently indisputable case of uterine bleeding in a castrate following the administration of only 2 mg of dihydroxoestrin has however been reported (Werner, A A, *et al*, *J Amer med Ass* 1937, 109 1027)

is usual it is by no means invariable. The following case histories are typical of many others in my possession.

#### ILLUSTRATIVE CASES

**Case 1**—Mrs C aged 65. This patient cannot remember exactly what her age was at the menopause—probably about 48. Had far too much to do to be bothered about that sort of thing. She put on a little weight at that time but had no flushes or any other symptoms. She experienced good health until two years ago when she became more easily fatigued and subsequently developed giddiness with falling so that she was afraid to go out of doors by herself. She also had insomnia, depression and slight puffiness of the ankles. Blood pressure 175/115. The patient was referred for special advice on account of her rapidly failing vision associated with pallor of both optic disks. The subjective symptoms cleared rapidly with 0.1 mg oestrone thrice daily by mouth with six injections of 1 mg oestradiol given twice weekly at the commencement of treatment. Six months later with correction she was reading 6/6 J1 in both eyes.

**Case 2**—Mrs W aged 68 thinks the menopause must have occurred near the age of 46 since her little girl was about 2 years old at that time. She may have experienced occasional flushes about then but was not inconvenienced in any way. She always enjoyed good health until five years ago when she had an attack of sciatica. Shortly afterward symptoms of rheumatism began in the fingers and for the last three years she had suffered from recurrent neuritis of the arm pain and stiffness in the knees, insomnia, little sleep and mental depression. The rheumatism on account of which she first presented herself had previously been treated unsuccessfully with gold and physiotherapy. She failed to show any decisive improvement from small desensitizing doses of vaccine and was accordingly placed upon 0.1 mg oestrone three times daily by mouth. In three months she was able to kneel and rise without pain and her fingers though much deformed were also painless. The patient protests against any suggestion that treatment should be discontinued since with it she feels so much stronger, more energetic and more cheerful.

**Case 3**—Mrs L aged 70. She does not remember the date of the menopause but thinks it must have been about the age of 50. She cannot recollect any symptoms at that time. Her health was excellent until three years ago when her age began to tell on her heart. She suffered from palpitations, shortness of breath on exertion, oedema of the ankles and to a lesser extent of the wrists, insomnia and mental depression. There was also some pain and stiffness in both knees. The heart was found to be much enlarged and the first heart sound was of poor quality. The blood pressure was 165/120. She was given 0.1 mg oestrone three times daily by mouth with 1 mg oestradiol intramuscularly twice weekly and within six weeks she had lost all subjective symptoms. The oedema had disappeared and her usual optimism and ability to sleep had returned. She has continued to improve during the last six months.

**Case 4**—Mrs R aged 70. The menopause occurred at about the age of 50. She suffered from occasional flushes at that time and has had pericardial rheumatism of the knees with muscular rheumatism for the last six years with dizziness, headaches, insomnia and depression for two years. The subjective symptoms were rapidly controlled with 0.1 mg oestrone thrice daily by mouth and 1 mg oestradiol intramuscularly once a week.

It will thus be seen that while the menopause was undoubtedly accompanied in these cases by occasional mild phenomena such as hot flushes or some gain in weight the onset of that wide assortment of nervous symptoms which characterizes the climacteric was delayed for fifteen years or more.

#### Conclusions

Both on theoretical and on clinical grounds therefore it is important to differentiate between the climacteric

and the menopause. The former unlike the latter is not an epoch but an era; it represents not a simple change but rather the summation of innumerable independent factors; it is a chronic state of potential nervous disharmony which need of necessity bear no relation to the menopause but which may mature or be activated many years later. Ten years ago these considerations might have been thought of academic interest. To-day however they possess a practical significance which it is difficult to overstress.

Good health depends upon normal function. The importance of abnormal function in the production of morbid symptoms and morbid structural change is great and is by no means fully appreciated. The function of the body is the expression of its physical constitution of which the neuro-endocrine pattern forms the backbone. Just as the constitution is modified in the first third of life by the endocrine changes of adolescence so the functions of the body are modified in the last third of life by the changes of the climacteric. These functional changes are responsible in later years for the facilitation of many diseases and the causation of much ill health. It is true that the exact nature of these changes defies analysis and will continue to do so for many years to come but the means for the relief of much suffering is already to hand. A ray gonadotropic preparations, insulin, thyroid, testosterone, luteal hormone and oestrogen all have their place in the treatment of these conditions. The employment of these remedies will vary according to the requirements of the individual cases and in the absence of any measurable indicators is largely a matter of detailed clinical analysis and not a little experience. While financial considerations may limit the use of certain of these preparations such restrictions seldom apply to oestrin. In those cases where the symptoms of the natural climacteric may be attributed mainly to lack of this hormone its replacement can when necessary be effected entirely by injection and be administered by the patient, relatives or district nurse. There are very few cases whose requirements exceed 1 mg of oestradiol two or three times a week while the majority may be kept comfortable on less. Such treatment cannot be regarded as a luxury any more than can the treatment of the diabetic by insulin. It is wrong to regard the various disturbances of the climacteric as innocuous or tolerable and therefore to be tolerated. Rather must they be looked upon as a warning of potential organic changes which if disregarded may ultimately lead to premature degeneration of all tissues particularly the heart and kidneys.

I have endeavoured to emphasize this distinction between the climacteric and the menopause in order to counteract the common impression that indications for endocrine and particularly oestrogen therapy are limited to a short period which follows the cessation of the menses. The delayed or late climacteric is by no means uncommon and much suffering can be spared by a wider appreciation of the virtues of oestrin in its treatment.

## Clinical Memoranda

### A Successful Femoral Artery Embolectomy

Successful cases of arterial embolectomy are still rare enough to justify the publication of the following notes

#### CASE RECORD

A woman aged 39 was suddenly seized with severe pain in the right knee at 10 p.m. on November 12, 1937. At 10.30 p.m. she was seen by Dr R. D. Miller, who, at 1 a.m. the next day, sent her into the Hull Royal Infirmary with a diagnosis of embolus in the arteries of the right leg. The patient was known to be suffering from auricular fibrillation associated with mitral stenosis of rheumatic origin, and about eighteen months previously she had had a 'stroke,' resulting in a left-sided hemiplegia. This was presumed to be due to a cerebral embolus.

On admission the patient presented the classical triad of pain, pallor, and paralysis, with some loss of sensation and absent pulsation of the distal arteries of the right leg. The pain was so agonizing that she cried for relief. The pallor was very marked from the knee downwards and less so in the thigh. The paralysis was incomplete, and this also applied to the loss of sensation. There was strong pulsation in the right common femoral artery, but nowhere else in that leg. It was obvious that the arterial circulation of the right leg had been suddenly and completely occluded by a clot but there was some uncertainty about the exact position of the latter. The concentration of the pain at the right knee, however, and the well-marked pulsation of the common femoral artery just below Poupart's ligament suggested that the termination of the popliteal artery was the most likely site of obstruction.

**Operation**—This was begun at 1.15 a.m. (about three and a quarter hours after the onset of symptoms) under spinal anaesthesia. That method was employed in preference to the usually advocated local anaesthesia owing to the fact that some sensation was present in the leg and that the site of the embolus was in doubt. The popliteal artery was first exposed and was found to be collapsed and pulseless, so this wound, which was quite vascular, was left open and the common femoral artery exposed in Scarpa's triangle. There was a little bleeding in this incision, but less than normal. The common femoral artery was found to be distended and to be pulsating vigorously as far as the bifurcation into its terminal branches which were collapsed. Just above the collapsed artery the outline of the embolus could be seen and felt. The common superficial and deep femoral arteries were carefully mobilized and thin rubber bands were passed behind them to act as tourniquets. Throughout the operation the wound and the instruments were kept soaked in a 2 per cent solution of sodium citrate. A longitudinal incision 1 cm in length was then made in the common femoral artery just proximal to the embolus which was carefully removed with fenestrated forceps. The clot was found to be in two pieces which were blocking the superficial and deep femoral arteries. The upper tourniquet was now momentarily released, whereupon a huge spurt of blood showed the proximal circulation to be free. The incision in the artery was then sutured with a continuous row of through and through stitches the suture material being fine vaselined silk. Release of the tourniquets showed haemostasis to be complete. The first incision was now examined and was found to be bleeding while the popliteal artery was pulsating strongly so haemostasis was obtained and both wounds were closed. The foot and leg had by this time become pink and warm. In closing the upper incision a stout piece of silk was passed under the common femoral artery at its upper end and brought out of the wound. This was to be used in the event of a secondary haemorrhage which fortunately did not materialize.

Convalescence was uninterrupted. On the first and second days following operation the pulsation of the popliteal artery was easily palpable and although subsequently the impulse was felt only with difficulty the leg itself remained warm and pink suggesting that the artery had remained patent.

#### DISCUSSION

Most of the statistics dealing with arterial embolectomy are taken from a series of 382 Swedish cases published by Einar Key and these show that the termination of the common femoral artery is the most frequent site for embolic obstruction, accounting for some 54.5 per cent of all cases.

The prognosis as a rule is bad, and in any one individual case is dependent on the following factors:

1 **Time**—Cases operated on within six hours have a fair chance of recovery, but after six hours the mortality rate of the limb and the patient rises rapidly. A successful case has however, been reported in which the operation was done sixteen hours after the onset of symptoms.

2 **General Condition of the Patients**—These patients are often suffering from carditis with decompensated valvular lesions, and therefore make poor subjects for operation.

3 **Site of Embolus**—The best results have been obtained in the axillary and brachial arteries, with a 44 per cent operation success. The femoral and popliteal arteries come next with a 20 per cent chance of recovery.

4 **Condition of the Artery**—Previous arteriosclerosis and rough handling of the vessel during operation are both apt to result in post-operative thrombosis of the affected artery. This is far more serious than ligation of the same vessel, since thrombosis tends to spread up and down the artery, thus interfering with the collateral circulation as well as the main stream.

Only about a dozen successful cases of arterial embolectomy have been reported in this country, and although a much larger number must undoubtedly have been carried out we are still behind the Scandinavian countries in this branch of surgery. The remedy is simple: early diagnosis and immediate operation.

I am indebted to Mr J. N. Young and Dr R. D. Miller for permission to publish these notes.

At the March meeting of the Central Midwives Board for England and Wales the following were appointed regular examiners at the London Centre: A. C. H. Bell, M.B., F.R.C.S.; J. D. S. Flew, M.D.; Dame Louise Mellor, M.D.; J. V. O'Sullivan, M.D., F.R.C.S.; N. L. White, M.D., F.R.C.S. Approval was granted to the Central Middlesex County Hospital and Westcotes Municipal Maternity Home, Leicester, for the purpose of providing instruction in the essentials of obstetric analgesia and in the use of a recognized apparatus.

## Reviews

### METHODS IN CLINICAL PATHOLOGY

*Approved Laboratory Technique* By John A. Kolmer  
MD DPH ScD IID LHD FACP and  
Frederick Boerner VMD Second edition (Pp 893  
380 figures 12 plates 30s net) New York and  
London D Appleton-Century Company 1935

Variations in laboratory technique even in simpler routine work are endless and even the most enterprising and enlightened clinical pathologist has something to learn from others if he but knew it. Among the better bench books designed to spread the most useful information of this kind is Kolmer and Boerner's *Approved Laboratory Technique* which now appears in its second edition. This work was originally prepared under the auspices of the American Society of Clinical Pathologists and in its present form it has the sanction of twenty-eight named collaborators as well as in many cases of the originators of the methods described. It covers the whole range of laboratory investigation in relation to medicine including not only haematology bacteriology morbid histology and chemical pathology but toxicology and less readily classifiable methods such as tests for pregnancy while there are useful chapters on general laboratory management including the cleaning of glassware the use of the microscope and the handling of animals. Adequate emphasis is laid on the need for collecting specimens by proper methods and these methods are fully described. Serology has a full share of attention and added space has been devoted in this edition to mycology and parasitology.

Individual preferences are such that no one is likely to agree with each and every statement in this book but most of the procedures described are doubtless the best of their kind. A few methods of doubtful value are included such as Rivalta's test for serosamucin. Alternative tests are sometimes given with no indication of which is considered the better. The lists of bacteria which may be grown from different materials are not very helpful and frequently include non-pathogenic species and no mention is made of the desirability in interpreting agglutination tests of knowing the degree of agglutinability of the bacterial suspension used. With few exceptions such as these we find nothing to criticize and it can be said without hesitation that this work is a valuable practical guide. Its usefulness is increased by profuse and apposite illustrations.

### EXPERIMENTAL SURGERY

*Textbook of Experimental Surgery* By J. Markowitz,  
MB Tor Ph.D MS in Exp Surg. Minn. (Pp 528  
330 figures 31s 6d) London Baillière Tindall and  
Cox 1938

A textbook of experimental surgery fulfils a great need in laboratories where animal experiments are carried out. To obtain the details of various technical procedures requires much searching of the literature often only to find that important parts of the operation are described scantily or dismissed in a few lines. Dr Markowitz has attempted to fill the gap and for what he has done laboratory workers in the English speaking countries will be grateful. Unfortunately the book suffers from the injection at intervals of such sentences as: 'The scientific equivalent of worshipping Mammon is to worship an engine and Reader as de Quincey might have asked in his curiously overwrought but beautiful way: What is a plethysmograph? You who do not pretend to cumber-

some erudition and who have enough to do to keep up with the facts of surgery without branching into the technique of physiology be not ashamed (as de Quincey might again have said) if you do not know.

Details of all the usual instruments necessary for experimental surgery are given but Dr Markowitz omits scissors. Why? Bodie's table is recommended as the most useful but the figure illustrating this bears little resemblance to Bodie's original design. Sutures is considered but it is confusing to read on one page the continuous suture is therefore better for closing an incision than a lock suture and four pages later we do not recommend a continuous (Glover's) suture. Sentences referring to the closure of an incision. In a chapter on thoracic surgery it is stated that emphysema is the usual complication of thoracotomy in the dog. This is not the experience of at least one laboratory in this country where in a series of over 100 thoracotomized dogs this complication never arose. The modern method of pressure anaesthesia for thoracotomies is not mentioned in the text. Various operations which are carried out inside the chest cavity such as vagotomy, bronchotomy and splachnectomy are not described nor is any reference made to experimental work in this country on the oesophagus. O'Shaughnessy's experimental studies on cardiac surgery are not mentioned.

In spite of its many defects this book will prove useful in laboratories where animal experiments are conducted but it must be realized that while it gives in detail the experience and practice of one large laboratory of experimental surgery the experimental procedures recommended and described are not the only good ones in evidence nor can the practice of other laboratories in this country be ignored. This book should be a stimulus to British experimenters to compile a textbook which will cover the whole field and include experimental procedures on animals other than the dog.

### FORM-GIVING GYMNASTICS

*A Text Book of Gymnastics (Form giving Exercises)* By  
K. A. Knudsen Translated by F. B. A. Hansen (Pp  
364 216 figures 12s 6d) London J and A Churchill  
Ltd 1937

The widespread publicity given to the Government's physical fitness campaign has stimulated interest in physical education to an extent never before experienced and it behoves those concerned with the public health to understand fully what measures are desirable and what it is possible to achieve. An astonishing amount of vagueness exists concerning physical education and in many minds the mention of it wakes only a blurred image of excessively active arms and legs against a black ground or widely opened windows in the zero hours of a cold morning. To blot out this depressing image and replace it by a positive conception of the aims and possibilities of a constructive system of gymnastics medical practitioners and students can be strongly advised to read Knudsen's *Text-Book of Gymnastics*. Among the many that have been published recently this book is outstanding as one which combines an idealistic outlook with an intensely practical and rational scheme of work. We expect a high standard in Danish books on educational subjects and this one written by the former chief professor of physical education in Denmark maintains the record of achievement.

The book deals particularly with form giving gymnastics based on the Ling system and consequently its special aim is to mould and develop the body harmoniously. The spine and the joints and muscles concerned in a normal

ments, being of primary importance. This method is in opposition to the various gymnastic systems which tend to overdevelop single groups of limb muscles (for instance, the much-displayed biceps) and neglect the trunk and body as a whole. The exercises described are exacting for the teacher because they are apparently simple and not spectacular. Much keenness is needed to convince the class that their true aim is to prevent deformity by controlling bodily development and to correct incipient deformity. The chapter on the back, which precedes those on the form-giving exercises, is a valuable one and will be appreciated especially by those who have to examine numbers of school children. There are sections on "order exercises" and on game-like exercises suitable for children, but among these it is surely unnecessary and undesirable to describe one as "lunging to war." The photographs illustrating the exercises are good though rather small, and the anatomical diagrams and radiographs of the body in various positions are a welcome feature to students who have come to realize that they know very little of the action of muscles in spite of all the time spent in learning detailed anatomy.

Among the special exercises described for the back the spin-bendings are dearest to the author's heart, for they are the most valuable of all, and he urges parents to give their children sets of wall-bars at the earliest opportunity. He feels that rhythmical work, although attractive for children, is not sufficient for their development, and if given exclusively is apt to result in slipshod, "sloppy" action. The author is insistent that physical education should primarily be concerned with the individual and is therefore unsuitable for spectacular class shows. Physical training that is good for the various individuals in a class seldom makes successful show-stuff. Schools, please note!

## VITAMINS AND HORMONES

*Ergebnisse der Vitamin- und Hormonforschung* Vol. 1 Edited by L. Ruzicka and W. Stepp. With a Foreword by Sir Frederick Gowland Hopkins. (Pp. 470, 44 figures. RM 33 bound, RM 34.) Leipzig: Akademische Verlagsgesellschaft M.B.H. 1938.

In this monograph on the vitamins and hormones recent developments in these studies are brought together in the form of brief reviews by people who have been working closely on each subject. It is essentially a series of contributions from experts rather than a unified whole. Sir F. Gowland Hopkins contributes a reminiscent foreword. The emphasis is almost entirely biochemical rather than clinical. E. Glanzmann of Berne contributes a section on important vitamin problems in childhood. Vitamin C is dealt with by D. Giroud of Paris, vitamin B<sub>1</sub> by R. R. Williams of New York and the remainder of the B vitamins by C. A. Elvehjem of Madison; the vitamins concerned with reproduction are dealt with by H. Guggisberg of Berne. H. von Euler of Stockholm contributes a section on the significance of enzymes in cell life. The hormones are represented by a discussion of the chemistry of posterior lobe hormones of the pituitary gland by R. L. Stehle of Montreal, a section on the interrelationships between the hypophysis and the sex glands by W. Berblinger of Jena, the chemistry of cortin by T. Reichstein of Zurich and sections on the chemistry of the male and oestrogenic hormones contributed respectively by M. W. Goldberg of Zurich and G. F. Morrison of Toronto. Each author uses his own language.

The rather strictly biochemical bias of the book makes it of greater interest to those who are engaged in bio-

chemical and strictly biological research than to the clinical worker. Work upon the vitamins and hormones has become so complicated and specialized that there is a positive value in bringing together contributions from so many different fields. As Sir F. G. Hopkins says, it is logical that vitamins should be associated with hormones in a volume such as this. The brevity required to fit so many contributions into a single volume has the disadvantage of making some of them incomplete. It is surprising, for example, to turn to the section on anti-anæmic factors in the contribution on the B vitamins and to find that there is no reference at all to the interesting problem of the nature of the extrinsic factor involved in the aetiology of pernicious anaemia.

## RUDIMENTS OF ANATOMY

*Fundamentals of Anatomy* By Carl C. Francis, A.B., M.D. (Pp. 320, 176 illustrations, including 26 coloured plates. 12s. 6d. net.) London: Henry Kimpton, St. Louis: C. V. Mosby Company, 1937.

This elementary book by Dr. Carl C. Francis of the Western Reserve University, Cleveland, is designed to give the student a general knowledge of the essentials of anatomy. It is clearly written and illustrated, many of the figures having been specially drawn from specimens in the museum of the Western Reserve University. As stated in the preface, it is evident that "every effort has been made to keep the text concise." In effecting this, however, much that in our opinion is vitally essential has been omitted, and many details of anatomy a knowledge of which is important for the operative work of a practical surgeon are lacking.

In this type of book brevity in many instances leads to a mere enumeration of facts which, without any explanation of their practical or scientific bearing, become devoid of interest. We need only mention as an illustration of our meaning the additional interest which is brought into the study of the odontoid process of the axis vertebra when something is told of its mode of development and phylogeny. In justice, however, to the present work we may state that the text as a whole is remarkably free from errors, and that it contains in a very limited number of pages a large amount of information which is expressed in a simple, lucid style, and that this, combined with the clear printing in full of the names of the parts indicated in the illustrations, should prove of the utmost value in saving the reader time and trouble. Books of this type should prove serviceable as an introduction to anatomy for ambulance workers and nurses, but in our opinion the descriptive anatomy for medical students cannot be cut down to a minimum without seriously lowering the general standard of medical education.

## APPLIED MYCOLOGY AND BACTERIOLOGY

*Applied Mycology and Bacteriology* By L. D. Galloway, M.A. Cantab. and R. Burgess, M.Sc. Ph.D. Lond. (Pp. 181. 10s.) London: Leonard Hill Ltd. 1937.

Although it is a truism to say that microbiology has many important applications, it is one which is not always fully appreciated. We in medicine are apt to forget that, while the study of micro-organisms developed principally in its application to medicine, bacteria and fungi have other activities no less important to man. This one-sided development of microbiology and more particularly bacteriology, has been remedied to a considerable extent of late years, the study of bacteria and fungi in relation to agriculture and industry receives more and more attention. Undoubtedly there are many whose work brings

them into contact with microbiological problems but who are debarred from taking an intelligent interest in them owing to a lack of knowledge and it is for such people that Messrs Galloway and Burgess have written this small book.

The authors begin with a brief description of bacteria and fungi and their classification. This is followed by chapters devoted to the technical side of the study of micro-organisms and the first part of the volume closes with chapters on the metabolism of bacteria and fungi and the methods available for the control of these micro-organisms. Part II is concerned with the applications of our knowledge of bacteriology and mycology to the food industries to fermentation textile industries medicine and agriculture. Naturally in the space of 173 pages these matters can only be treated in bare outline but it is detailed enough for its purpose and the information given is well chosen and well arranged. For students of medicine its main interest is that it presents the study of bacteria and fungi in its true perspective and not solely in its relation to disease.

### Notes on Books

*Short Years The Life and Letters of John Bruce MacCallum M.D.* by ARCHIBALD MALLOCH is published in Chicago by Normandie House price 3.50 dollars. This charming record as shown by the letters and the running commentary of a talented medical man who though already distinguished as a histologist and a physiologist died before he reached his prime more than thirty years ago has evidently been a labour of love to the librarian of the New York Academy of Medicine Dr John who was a brother of W. G. MacCallum, the successor of W. H. Welch as professor of pathology at the Johns Hopkins University was a man of many interests. He was a good correspondent of the old fashioned model not of the concise telegraphic style of these days of universal hurry. His letters fortunately preserved by his family those to parents usually beginning "Dear Home" have been extensively utilized by Dr Malloch to tell the story of a life much handicapped and cut short by tuberculosis. With a circle of devoted friends he was cheerful and affectionate but his face showed lines of sadness and his notebooks and poems such as that beginning *Spirit of Death* now carved on his tombstone of grey granite bear out the accuracy of this index of the inner man. His poems as quoted in the volume are attractively arresting and two prose stories also incorporated here show talent of a rather unusual kind. He was an admiring pupil of Osler who nicknamed him "St John" and wrote of him "He was one of the most brilliant young men it has ever been my lot to teach."

The richly documented work entitled *Coming into Being among the Australian Aborigines* (London George Routledge and Sons Ltd 21s) by Dr M. F. ASHLEY-MONTAGU assistant professor of anatomy New York University is as its subtitle indicates a study of the procreative beliefs of the native tribes of Australia. The author has tried to collect all the available evidence relating to the procreative beliefs of the Australian aborigines and he confirms the truth of Spencer and Gillen's observations published in 1899 that there are aboriginal people in Australia without any knowledge of the relation between coitus and pregnancy. The objections which have been raised against the existence of such ignorance are critically examined by the author who shows that the procreative beliefs of the Australians form only a special case of the belief in the supernatural birth which is by no means peculiar to Australian aborigines. In a

chapter on phallic ceremonies or so called phallic worship it is shown that their performance so far from indicating a knowledge of the relation between intercourse and pregnancy is merely a ritual sort of sexual pleasure while in the following chapter on the operation of sub-incision or slitting open the penile urethra on its ventral surface the author maintains that the operation is no intended as a contraceptive measure but was instituted to cause the male to resemble the female with respect to the occasional effusion of blood and possibly to produce some termination of the male organ. Professor Malinowski to whom in conjunction with Professor Westermarck the volume is dedicated recommends it as the best introduction to anthropology indeed to the study of social science.

Professor HARRY BECKMAN'S well known volume *Treatment in General Practice* has now appeared in a third edition revised and entirely reset (Philadelphia and London W. B. Saunders Company 42s). Though many more items are included in it the text occupies fewer pages than its predecessor of 1934. The book contains a great deal of close packed information every disease is given its separate heading and the appropriate treatments are set out in some detail. There are a number of new sections others are regrouped and obsolete matters are now wisely omitted as being out of place in a book whose scope is already quite large enough. A further lease of popularity seems assured.

### Preparations and Appliances

#### ETHYL CHLORIDE ANAESTHETIC MASK AND HOLDER

Dr P. E. WOODROOFE (Bradford) writes:

This mask obviates the necessity for using both hands for the administration of ethyl chloride by combining a mask and a holder for the ethyl chloride bottle. As I consider there should be continuous spraying till the depth of anaesthesia required is attained the angle of the holder to the mask has

been so devised that whatever the position of the patient the ethyl chloride bottle is in action to the last drop. The holder is grooved so that the contents of the bottle can be fully observed. The mask and holder are chromum plated light and durable. The mask is made in two sizes—medium for adults or older children and a small one for younger children. The holders which fit the former have been made to fit the standard ethyl chloride bottles. A strip of rubber or felt can easily be inserted for any bottle not fitting into the holder. A garment tie pad can easily be secured to the mask by a rubber band at each end. Further details may be obtained from A. Charles King Ltd., London W.1. whom I wish to thank for their co-operation in making this instrument for me.

## PHYSICAL EDUCATION\*

BY

VISCOUNT DAWSON OF PENN, M.D., P.R.C.P.

As regards modern days, physical education may be said to have originated in Denmark, when in 1804 it was made an essential part of the curriculum in the national schools. Soon after came Ling, who designed a scheme of gymnastics based on his study of anatomy and physiology, and in 1813 became Director of a Central Institute in Stockholm. From this parent system physical training extended into various countries and developed in accordance with the needs and ideas of different communities. On the other hand, in Great Britain, so long and pre-eminently the home of games and sports, the idea of physical education fell on stony ground, and this country remained absorbed in its own ways.

In the course of the years which followed, Ling's system was found to be too static, formal, and sombre, muscular effort being regarded as an end in itself, and so arose in the year 1915 the gymnastic movement in Denmark of which Niels Bukh was the founder. Niels Bukh used planned exercises (gymnastics) to secure good posture, muscles strong and apt for the functions they had to serve, and rhythmic gymnastics to teach balance and grace of movement. On this basis of designed and directed training Bukh employed athletics, games, and folk dancing as a means of its expression. Thus was secured not only strength, suppleness, and even beauty of frame—the body giving the quick expression of the mind's behest—but also the team spirit, and withal joy in the doing.

### The English Paradox

It is interesting here to note that this system of Niels Bukh—namely, a combination in varying measure of physical training with games and sports—is, in Great Britain, held to be the correct comprehension of physical education. Indeed, in most countries physical training is organized side by side with games, sports, and the cult of the outdoor life. Meanwhile, England has presented a curious and conflicting spectacle.

On the one hand, the Board of Education, starting from small beginnings about thirty years ago, has steadily extended its field of physical education. With knowledge gathered from the great war it reformed its conspectus in 1919, and to-day physical education, based on a notably widened syllabus of 1933, occupies an important place in the curriculum of the elementary schools, though the Board of Education urges that existing facilities are far from adequate. Further, the Army School of Physical Training at Aldershot has during this century, acquired increasing reputation and influence. On the other hand, our public schools and universities have, for the most part, held obstinately to the view that their traditional and great institutions of games and sports are all-sufficing, and they have been slow to admit that these need to be supplemented by planned basic physical training.

Amid this divergence of opinion and practice of the Board of Education and the public schools and universities, public opinion has remained indifferent until this recent generalized awakening to the conviction that the standard of national fitness can and must be raised and that in large measure this can be achieved by physical training, games, sports, the provision of playing fields, and, in general, the cult of open-air activities. As is natural this rising enlightenment lacks as yet a direction proportional to its force and so carries with it the risk of unguided and ill-judged efforts which might detract from the benefits to health so keenly desired and expected.

Thus arises the importance of the medical profession making this subject its own, as bearing on the constructive health of the nation for the knowledge of the development and growth of the body rests on the medical sciences and there is a large field which, in the interests of physical education needs to be explored. The medical man is an educationist of the body, just as the schoolmaster is an educationist of the mind, and they must work together.

The Government, convinced that the development of better physique was essential to the welfare of the nation, had the alternatives of imposing a plan of physical education from the centre or of integrating existing local activities by propaganda and money grants. The latter course, which was the one adopted, has the disadvantage of being slow and cumbrous, and of provoking impatience and charges of inertia from lookers-on. On the other hand, the adoption of a central plan would have disorganized innumerable local activities, antagonizing rather than enlisting their sympathies and might have raised the bogey of disguised militarism. And so the National Council for Physical Fitness pushes forward, under the able guidance of Lord Aberdare and Captain Ellis, with the building up of a nation-wide scheme of educative and recreative physical training.

### Relation between Physical Training and Games

Team games and sports which carry no conscious purpose of physical training but are played for their own sake and the love of the game, excel in training the mind in alertness, concentration, and decision, the body to quickness of response, and in arousing a sense of joyous struggle coupled with the discipline of playing for the side—together a harmony of body, mind, and character. On the other hand, proficiency in games is compatible and often exists with defects of frame or function. Even though such defects may not make themselves felt at the time they may easily become a progressive handicap when manhood is reached. Again, games, unless correlated with basic physical training, can overstrain their votaries. The frame of a youth whose spirit outstrips his strength can be damaged by over-devotion to sport, and especially to one sport. With games in schools there is a tendency to focus attention on the boys who have the aptitude to play well. This, however inevitable, makes it the more necessary that the boy who is mediocre or dull at games should receive adequate physical training, or he will leave school with an uneducated body. And well-taught physical training is no dull exercise, but quickens and interests the mind and brings the exhilaration of effort. The same consideration applies to those classes of people whose opportunities for games and sports are scanty.

Sports and games are the fulfilment of physical training and should rest upon it, for planned physical exercises increase the strength, control, and response of the body and improve the form and style of the athlete. Moreover, physical training develops certain qualities which are basic to sound physical education such are posture, poise, flexibility and rhythm of movement, and efficient respiration.

### Posture

Good posture, whether standing or sitting, is not an innate quality. It has to be taught. This may be due to the fact that the development of the erect attitude is a recent chapter in the history of evolution. Good posture is characterized by stillness though not stiffness. It is effected by muscular tone, a reflex made up of afferent impulses from the sense organs of the muscles and, less important, from the ears and eyes, to the brain and efferent impulses which emerge from the cells of the anterior horns. The discharge of the efferent impulses for the maintenance of this muscle tone would only need to be slow, and therefore could be the longer maintained without muscle fatigue. It is said that the oxygen consumption and carbon dioxide output of muscle so

\* Opening address in a discussion at the Section of Physical Medicine, Royal Society of Medicine, March 18, 1938.

functioning is only 25 per cent higher than that of paralysed muscle. Training gives to the various groups of muscles which together maintain good posture—say, in the erect position—strength, control and co-ordination; there thus arises a postural sense which prompts the right balance of muscular tone. Good posture at first the result of conscious effort maintained by the cortex passes gradually into an unconscious habit (reflex) maintained in the mid-brain and as it does so makes manifest in ease of effort a balance and poise which give to the body strength and beauty. Good posture is then assumed naturally whenever movement ceases and gives repose without producing fatigue.

It may almost be said that given good posture and good carriage (gait) all other things shall be added unto you for these are the conditions which enable the body to grow up symmetrical and flexible, pursuing its activities with ease and graceful effort and allowing the possessor to hold his head erect and go through life with confident step. Thus do body and mind move together.

To maintain good posture muscles and nerves must be well nourished and adequately rested. This means food adequate in quantity and quality, sufficient hours of sleep—often lacking—fresh air and recreation which gives the body exercise and the mind diversion. And side by side with the muscle tone of good posture is needed the aptitude for muscle relaxation which is precedent to repose of mind. So often muscles and mind remain taut after work has finished—a frequent cause of strain and exhaustion. For a study of good posture standing or sitting or again of complete relaxation witness a well-bred sporting dog.

#### Physiological Foundations

No system of physical training so far put forward has rested or could rest wholly on physiological data; rather have the methods been evolved from observation and experience from the days of Ling onwards. The time has come for them to be surveyed and where necessary modified in the light of firmly set physiological knowledge. Though it is right there should be a lag between the conclusions of experiment and practice the lag here is too long.

Research into various aspects of educative and recreative training increases each year; in particular the field of knowledge has been enriched by a study of athletes—for instance in the spheres of metabolism, circulation and breathing. I will put forward certain illustrative examples for the purposes of discussion. It is known that sugar given to soldiers on long marches enables them to carry on longer without fatigue. Hansen has found in experiments on athletes that to obtain the maximum output there should be two days rest before the effort so as to raise glycogen reserves to their highest point. Sugar given at the time of the effort is not so effective. Next the period of rest needed after a big effort. Boigevy gives the results as follows:

After a 100 metre race the rest required varies from half an hour to two hours. After a 3 000 metre race lasting nine to eleven minutes it ranges from three to fifteen hours according to the training. On the other hand results of observations on blood pressure before and after athletic efforts are varied and discordant and some of the figures do not agree with the experience of clinical practice.

There seems to be agreement that during training the basal metabolic rate increases. As training reaches its completion does the rate decrease? It should do so as the machine runs in—that is works more efficiently.

#### Metabolism of Muscle

Passing to the metabolism of muscle may I recall that glycogen hydrolyses into glucose, glucose combines with phosphoric acid to form lactacidogen which in breaking

up into lactic acid and phosphoric acid releases the energy for contraction. After contraction oxygen comes into the picture and breaks down the lactic acid into carbon dioxide and water (though only to the extent of 20 per cent with a full oxygen supply). Unless for example there is an adequate supply of oxygen the lactic acid content increases till sooner or later it reaches the fatigue reading. After the start of an exercise (for example gentle running) if the lactic acid content of the muscles is not to increase to the point of fatigue there must be a larger supply of oxygen from the blood and therefore from the air. Soon this supply reaches its limit and then the supply and expenditure of oxygen are balanced. But the body can incur an oxygen debt by delayed payment and exercise can continue. The limit of debt will vary from a few cubic centimetres to 12 or more litres according to the subject and his degree of training. Thus (to quote Griffin) a man's ability to take in oxygen from the air and to accumulate an oxygen debt determines how much strenuous work he can do without exhaustion. Here then thanks to A. V. Hill and his collaborators there comes into view a scientific basis for physical training.

The supply of oxygen to the muscles depends (a) on the power of the blood to load and unload oxygen—a power which is increased by fresh air and exercise; (b) on the output of the heart and blood vessels; (c) on the efficiency of respiration measured in part by the vital capacity. This last depends more on the flexibility of expansion than on size of chest, on the thorax moving not as a whole but by its individual parts, on the intercostal muscles and diaphragm being strong and well co-ordinated. These circulatory and respiratory processes belong to the sphere of basic physical training, which will condition success in games and sports.

#### Training of Teachers

I have endeavoured by the foregoing illustrations to show the importance of the newer knowledge with which physical education needs to be brought in contact and it will be agreed that education and research should go hand in hand. If this is to be a nation-wide movement there must be not only more but the best provision for the training of teachers and others concerned in educative and recreative training. Our existing services of physical education and their leaders and teachers, and high in reputation but these services have not been accepted as of prime national concern in the way that Sweden and Denmark have accepted theirs for generations past and with great benefit to the well-being of their people.

It is public knowledge that our Government has decided to establish a national school of educative and recreative training and that the Board of Education is actively concerned with the realization of that project. Here teachers of anatomy and physiology will work side by side with teachers of physical training—science and art harnessed to the same chariot. Here will be studied the total functional value of the individual having regard to his make-up and environment. And more—physical education will concern itself with the whole man in the words of Montaigne.

I would have his outward behaviour and manner and the disposition of his limbs formed at the same time as his mind. It is not a soul it is not a body that we are training up; it is a man and we ought not to divide him into two parts nor fashion one without the other.

Physical education if it is to go aright will need the responsible guidance of trained doctors. In the future those who aspire to be medical officers of schools will require to include in their training a knowledge of physical education and would profit by a course of instruction in the National College.

To my younger colleagues at the outset of their careers there is opening a new sphere of action. Whether viewed

as a specialty within general practice or as a part of those sociological aspects of medicine which are certain to come into increasing prominence year by year, it will be work of interest and usefulness, and from a scientific point of view the physiology of toil and leisure presents an attractive field of investigation.\*

And, lastly, the knowledge gained by trained observation and research at the college will also be available for those problems of work and recreation which arise with the development of modern industry. And may I repeat that physical education must never lose contact with the cognate subjects of right feeding and adequate repose, for the study of which the college will afford opportunities

### The Why and the Wherefore of Physical Education

It may be said—why this concern about physical education? Every man endowed with health, strength, and endurance is not only a life enriched in capacity for efficiency and happiness but *ceteris paribus* a citizen of greater value to the State. From the racial point of view the fact that civilization tends to preserve the weaklings and does not conform to the laws of sound breeding makes it the more important to train and multiply the fit and push them to the forefront, in fact 'planning' to this end must be the policy of a modern State.

Thus nurture and education both of body and mind, have a big task before them, and that task is heavier for certain sociological reasons—for instance (a) Increasing urbanization, with its limitations of space air, sunshine, and the greater tensiveness of its life (b) Increasing specialization in industry which leads to the over-exercise of a part of a man and the under-exercise of the whole man. Machinery so often demands concentration of attention in a limited and even monotonous sphere of action, while leaving the creative, thinking part of the mind barren—and with this a cramped body. Speed encourages the ready-made rather than the self-made in thought and action. And, in general, man's power of adaptation lags behind the rapid changes in material civilization. In 1933 Sir George Newman laid down five conditions fundamental for the success of physical training and the first of these was 'The Child Must be of Good Stock'. In this country we are ignoring the implications of this tyrannical fact, just as years ago we ignored physical training when Scandinavia was up and doing

### Measures we Might Take

Measures within our reach are pushed to the forefront the best of the youth—youth leaders would create a standard for their own generation, consider the granting of loans (already working in Germany) to medically approved marriages the obligation to repay being reduced with the birth of each child, institute motherhood clinics to give the light and leading of knowledge. In short, plan for quality of stock—a quality which would preserve the attributes of individuality and initiative.

Again, where posts and positions are filled through competitive examination such an examination should be a test not only of the mind but also of the body. Take entry into the Civil Service. It is part of the Government programme supported by all parties to promote physical education and national fitness. What an opportunity to put this programme into practice, and thereby bring fit and clever youth to the forefront, to the advantage of the service and nation. What an impetus this recognition of physical education would give! The world would go and do likewise.

Present medical examinations for entry into the civil services set out to ensure the absence of diseases and

defects. Rather should a physical examination answer the question "Which of these bodies are sound in structure and so well grown and so well trained as to carry out efficiently and well the mind's behests and in which order of priority would I place them?" We want no standard type of body. We need to recognize that there is an individuality of body just as there is of mind, we must think of quality, proportion, and effectiveness, not merely of size. A young man's body—his body—if sound well grown, and well educated, will not grow under effort but will enjoy it and be more likely to house a mind free, forthcoming and strong.

### TUBERCULOSIS SCHOLARSHIPS IN ROME

The Italian Fascist National Federation against Tuberculosis places at the disposal of the International Union against Tuberculosis six scholarships at the Carlo Forlanini Institute in Rome. The conditions are as follows.

These competitive scholarships, of a value of 2000 lire each plus board and lodging are intended to enable foreign medical practitioners to stay at the Carlo Forlanini Institute for the purpose of following a course of studies. This stage of eight months will correspond with the academic year (from November 15 to July 15) including the usual holiday periods. The scholars reside at the Institute.

The scholarships are preferably awarded to young physicians already familiar with tuberculosis problems who wish to improve their knowledge of this branch of medicine. The kind of work undertaken at the Institute will be subject to an agreement between the Director of the Institute and the candidate. Papers resulting from this work must be submitted for publication in the first instance to the editor of the *Bulletin of the International Union against Tuberculosis*.

The six scholarships will be awarded at the next session of the Executive Committee on July 11, 1938. The names of candidates, accompanied by particulars as to their age, qualifications, and professional experience, must be forwarded to the Secretariat of the Union, 66, Boulevard Saint Michel, Paris, not later than July 1. No candidature will be taken into consideration unless it has been forwarded to the Executive Committee by a Government or an Association belonging to the International Union. The address of the British National Association for the Prevention of Tuberculosis is Tavistock House North, Tavistock Square, W.C.1.

E. Burack and H. M. Zimmermann (*J. Nutrit.*, December 1937, p. 535) have investigated the effects of prolonged feeding of large amounts of cod-liver oil to rats and mice fed on controlled diets. Rats taking 27 per cent and 18 per cent of cod-liver oil in their food did not grow so well as those on a comparable diet in which the cod liver oil was replaced by peanut oil and vitamin concentrate. The adverse effect of the cod-liver-oil-containing diet was not countered by liberal intakes of yeast and was directly related to the amount of food consumed. Similar results were obtained in mice, but there was no correlation between body weights and food consumption. Of fifty-two mice fed for at least 150 days on diets containing 20 per cent of cod liver oil, some showed pathological changes—necrosis, fibrosis, or accumulations of phagocytosed fat or pigment—in heart, liver, and spleen, and slight changes in skeletal muscle, but there was no renal calcification. These changes were absent in the thirty-four control mice. The results in a small group of rats were similar but some control rats showed myocardial fibrosis. The authors incline to the view that the effects produced by cod liver oil are to be related to the irritant nature of the oil rather than to the production of hypervitaminosis, and conclude that the claims that cod-liver oil in therapeutic doses can do harm are not substantiated.

\* In this connexion I would point to the excellent work which has been done by the British Medical Association through its Physical Education Committee under the Chairmanship of Sir Kaye Le Fleming.

## PSITTACOSIS AGAIN

It is perhaps not generally realized that since the epidemic of 1930 died down cases of psittacosis have been occurring in this country. It is true that the number of cases has not been great but it is significant that there should have been any at all in some European countries less fortunate than our own—for example Germany—cases of psittacosis have been numerous. In view of the recent articles in the lay press concerning a suspected outbreak of psittacosis in the London Zoological Gardens it might be of interest to consider the mode of spread and control of this disease in the light of present day knowledge. The epidemic eight years ago was the result of the introduction into this country of diseased birds from South America. The investigations made possible by that epidemic showed that psittacosis was due to infection with a filterable virus which was excreted by the diseased birds in their droppings and the epidemiological data together with the fact that in the human disease the respiratory system was principally involved pointed to the respiratory tract as the portal of infection in man. From what was known then it was thought that this country could be kept free of psittacosis by strictly controlling the immigration of birds of the parrot family and in this conclusion we were not alone for other countries also placed an embargo on the importation of parrots and parakeets. This policy has failed and its failure is due to the fact that it was based on two assumptions both of which have proved false. The first was that the home bred birds were free from infection. Whether they were free from infection before the 1930 epidemic it is difficult to say probably they were not but they are certainly not free from psittacosis now. The second assumption was that a bird which appeared healthy and remained in good health during a period of quarantine was not infected and could safely be admitted to this country. This overlooked the possibility that healthy carriers of psittacosis might exist. Already in 1930 there was evidence that such a carrier state could exist in birds of the

parrot family for one of the cases investigated at the London Hospital was shown to have arisen from contact with an apparently healthy bird. Although the virus was not isolated from this particular bird and although it was thought that intimate contact between man and a healthy carrier bird would be necessary for infection to take place subsequent work has shown that the danger of infection from carriers is a very real one. The budgerigar in particular when exposed to infection tends to suffer from a subclinical rather than a frank attack of the disease. A carrier state is readily set up in these birds and it is from such apparently healthy carriers that many of the human cases have arisen during the last few years. There is perhaps a danger that the importance of this disease as a public health problem may be exaggerated. For some reason or other parrot fever has considerable news value and thus attracts a publicity which is hardly warranted by the number of cases that occur. All the same it is a serious disease with a high mortality rate and all possible preventive measures should be taken against it.

What then can we do effectively to control psittacosis? It is obvious that strict control of parrots and parakeets coming into this country with an adequate period of quarantine of those birds admitted is by itself inadequate. All this can do is to safeguard us against a repetition of the happenings of 1930. Possibly the periodic inspection of the stock possessed by bird dealers and the laboratory investigation of all deaths in birds of the parrot family with destruction of the contacts in aviaries or bird shops where there have been cases of psittacosis would in time materially reduce the incidence of the disease. But the public should know that the matter rests very largely with them. Those who do not wish to run the risk of this disease should not keep these birds in their homes and in this respect it should be pointed out that other species of birds such as canaries and various finches though not subject to psittacosis in the wild state are susceptible to this virus and will contract the disease when brought into contact with infected psittacines so that any such birds coming from dealers who possess a mixed stock which includes parrots and parakeets are suspect. What should be done to safeguard the public who visit the parrot houses in zoological gardens is another matter. There is no evidence that any visitor to the parrot house in the London Zoo has ever contracted psittacosis but in theory at any rate the danger exists. And in order to minimize or exclude this risk it might be advisable to take further measures than those hitherto in use.

## SHELLFISH AND THE PUBLIC HEALTH

The description by Lewis Carroll (C L Dodgson) of the young oysters—"Their coats were brushed, their faces washed, their shoes were clean and neat"—came to mind on hearing Dr R W Dodgson's account given at a meeting of the Epidemiological Section of the Royal Society of Medicine on March 25 of how shellfish have been persuaded to perform their own toilets in readiness for the human market<sup>1</sup>. It has long been known that if oysters are grown in estuaries they easily become infected with typhoid bacilli derived from sewage and it was found by artificial inoculation that the germs thus introduced survive in the body of the mollusc for several days. Dr Dodgson, who was lately director of shellfish services in the Ministry of Agriculture and Fisheries and is now consultant in that department said that without doubt shellfish from polluted beds are potential vectors of enteric fever and other diseases, and large numbers of people are suspicious of all shellfish on that account—a prejudice which sometimes becomes accentuated, as during the recent outbreak at Croydon. Some thirty, or forty years ago Conway mussels had an evil reputation, so much so that the fishery was closed in 1911. Experiments in artificial purification were then started, resulting in a satisfactory system which has been in continuous operation at Conway for twenty-three years, and elsewhere for shorter periods, and during the whole of that time no complaint of illness attributable to the purified shellfish has been received.

Dr Dodgson described the process of purification of mussels and oysters premising that the shellfish did not undergo any deterioration in taste or keeping quality in the process. The mussels are spread by the fishermen on wooden grids in large concrete tanks, and after hosing to remove mud are given a bath overnight in sea-water sterilized by chlorine and dechlorinated with sodium thio-sulphate and again hosed to remove dejecta. The procedure is repeated over another night, including a third hosing, and a final bath is given in treated sea-water to sterilize the outsides of the shells, after which the shellfish are transferred to sealed sterilized bags. The purification of oysters is just the same except that a multiple-jet hose is used to scour under the flat shells but in winter the purification of oysters is carried out in covered tanks, oysters failing to open, function, and eliminate satisfactorily at lower temperatures at which mussels are quite happy. The principle of the purification is merely that the shellfish are given baths of clean salt water in which they con-

duct unaided their own process. It is said that a single mussel can filter ten gallons of water in twenty-four hours. The secret of the efficiency of the purification process lies in the fact that the bacteria are discharged—imprisoned in the mucous material of the faeces and pseudo-faeces, which is practically insoluble in water. Several other methods of artificial purification have been devised, but most of them abandoned as failures or carried on only in a desultory fashion, owing to a failure to realize the physiological principles involved.

Coming to bacteriological considerations, Dr Dodgson put forward the view that the real criterion in judging the suitability of shellfish for human consumption was the pollutability of layings, bacteriological examinations being merely complementary and sometimes misleading. A standard of purity for purified mussels had been set up (namely not more than 5 lactose factors per 1 c cm of minced shellfish incubated at 37° C for twenty-four hours). Oyster purification judged by even this stringent standard had approached perfection, but with regard to mussels there had on three occasions been encountered anomalous periods during which the counts became fantastically high. No fault was to be found in the purification operations, and the mussels themselves were functioning vigorously and normally. All colonies tested during these periods belonged either to the cloacae or aerogenes types, and it was found that organisms of these types might at times multiply enormously in mussels, barnacles and raw sea water. Dr Dodgson's opinion was that these anomalous periods were not important in the public health aspect, and in any case, as there was no clue to the nature of the conditions determining them, it was impossible even to begin to legislate for them. Oysters had never shown any anomalous results, the fact that they carried no barnacles might be significant or might not. The possibility of the multiplication, or even bare survival, of organisms of the typhoid group has again been explored. Several strains have been used including the *Salmonella typhi* isolated in the Croydon outbreak. Neither in raw nor in autoclaved sea water has any multiplication been observed nor has survival beyond two or three days been noted.

Dr Dodgson considered that in view of recent findings there could be no legitimate standard of purity for purified shellfish based on tests carried out at a temperature of 37° C, in his view a satisfactory test could be found in incubation at 44° C, at which temperature all the citrate positives derived from shellfish—that is to say, the group comprising the "multipliers" responsible for the anomalous results—are eliminated. He mentioned the resolution passed in the Section of Public Medi-

<sup>1</sup> See also R W Dodgson *British Medical Journal* 1936 2, 169

cine at the Oxford Meeting of the British Medical Association in 1936, subsequently passed on to the Ministry of Health, urging the adoption of measures designed, in the interests of public health to grapple with the present unsatisfactory shellfish position. He submitted that failing a better method he had described which was approved by the Ministry of Health and the Ministry of Agriculture and Fisheries offered a ready means of putting such a resolution into effect. The method he said was simple and practically foolproof in operation and economically sound and experience over nearly a quarter of a century had afforded strong cumulative evidence that it was an adequate safeguard of the public health.

### EPHEDRINE

In his Sidney Ringer Memorial Lecture which appears in our opening pages this week Professor J. H. Gaddum propounds a new theory of the action of ephedrine. Ephedrine we may remember is built very like adrenaline and in a general way its effects are qualitatively similar. Professor Gaddum's theory is most rapidly grasped by considering the recent evidence that the parasympathetic nerves act by liberating acetylcholine the chemical transmitter of the nervous impulse when it has transmitted the impulse it is rapidly destroyed by an esterase. Now physostigmine or eserine has the property of inhibiting the action of this esterase so that after the injection of eserine impulses proceeding along parasympathetic nerves have a greater effect than before because the acetylcholine which they liberate is not destroyed so quickly. Nerves to striated muscle also act by liberating acetylcholine and physostigmine or the allied substance prostigmine is for the same reason beneficial in myasthenia gravis. In the sympathetic system the chemical transmitter is adrenaline or a very similar substance. Having transmitted an impulse adrenaline is then destroyed by an enzyme known as amine oxidase. Gaddum's theory is that ephedrine inhibits the action of amine oxidase so that after the injection of ephedrine sympathetic impulses exert a greater effect than before because the adrenaline they liberate is not destroyed so quickly. Hence Gaddum's suggestion is that the relation of ephedrine to the sympathetic system or more correctly to adrenergic nerves is like that of physostigmine to cholinergic nerves. The evidence for this view comes in the first place from the work of Blaschko, Richter and Schlossmann at Cambridge who have shown that amine oxidase destroys adrenaline but not ephedrine and further that in the presence of ephedrine amine oxidase does not destroy adrenaline. (It is however at present an assumption that amine oxidase is the principal enzyme which destroys adrenaline in the tissues.) Subsequently Gaddum and Kwiatkowski experimenting with rabbits ears perfused with Ringer's solution stimulated the sympathetic nerves and observed that during stimulation the venous outflow contained an adrenaline-like substance detectable by

a sensitive colorimetric test devised in Gaddum's laboratory by Shaw. When the nerves were stimulated in the presence of ephedrine the venous outflow contained a much higher concentration of the adrenaline-like substance. Gaddum and Kwiatkowski have also shown that ephedrine augments the effect of sympathetic impulses to the frog's heart to the rabbit's ear and to the cat's nictitating membrane. For the additional evidence for Gaddum's view the lecturer should be studied.

### THE SPAN OF LIFE

In the *United States Public Health Reports* of December 3 1937 there is an interesting summary of life tables constructed during the last 130 years from data collected in America. The early tables being based upon scanty material and constructed on unsound lines are merely suggestive but since the beginning of the century much has been done. The general results—a considerable increase of expectation of life at birth a lessening superiority of rural over urban districts—are similar to those of European experience. A point is however made which suggests some interesting reflections. The authors distinguish between the average number of years lived and the span of life—the maximum length of life attainable. So far as is known they remark there has been no increase in the span of life persons living to advanced ages do not live a greater number of years now than formerly. The exact length of the span of life is unknown. It is somewhat more than 100 years but how much more cannot be said. This subject has been recently discussed by the eminent mathematical statistician Dr E. J. Gumbel.<sup>1</sup> Dr Gumbel's work is mathematical and his definition of the extreme age involves the increase of this limiting age as the population increases (there are good reasons for this definition but they are of too technical a character to be discussed here). Like most mathematical students of the problem he dares not believe that there is any finite limit to age and the adoption of widely different hypotheses as to the relation between age and rate of mortality makes very little difference to the arithmetical results. None of his calculations brings one within sight of the traditional age of Thomas Parr perhaps the one person who secured admission to the *Dictionary of National Biography* solely by reason of longevity while from the reliable Swedish data his *dernier age* is found to be 104 years for males and 106 for females. A certain paradox of the method is that other things equal the worse the life table the greater the *dernier age*. A reason is that the better the mortality experience the less the scatter of deaths around the maximum. We seem to be tending towards the ideal humorously attributed by Mr Max Beerbohm to the Socialist State in which all men should live exactly the same length of time. But we are approaching this ideal without the need for living in a municipal lethal chamber. The approximation is however not very close and the theory might perhaps be improved. The obvious difficulty of any method is

<sup>1</sup> *Life, Death, Extremes and the Life Human*, P. L. H. Gumbel, C. 1937.

tion is the fact that data of mortality rates at ages over, say, 90 are scanty and inaccurate. Indeed most population life tables are at the oldest ages works of art rather than nature. Biologically speaking, our knowledge of the processes of senescence is very incomplete. It seems, on the whole, probable that the increase of the rate of mortality with age slackens, but the "law" of this is unknown. One has here a problem the statistical solution of which must depend upon increase of biological knowledge. As its practical importance, whether from a commercial or national point of view, is small, though its intellectual interest is great, no very striking progress can be expected.

### JUNGLE YELLOW FEVER

In 1932 a new factor of interest and importance came into the epidemiology of yellow fever. Before then it was held that this disease was typically urban and that *Aedes aegypti* was the only vector that need be taken into account, although since 1928 it had been known that other mosquitos, under experimental conditions, could transmit yellow fever by biting. Such transmissions were, however, thought to play no practical part in the natural spread of the disease. It was the outbreak of yellow fever in 1932 in the Valle do Chanaan in the State of Espirito Santo, Brazil, which first clearly demonstrated that some vector other than *Aedes aegypti* is capable of spreading the disease. This outbreak of "rural yellow fever without *Aedes aegypti*," and similar epidemics arising later in various parts of Brazil, Bolivia, and Colombia, commonly referred to as "jungle yellow fever," modified the opinion expressed by Carter,<sup>1</sup> that "owing to the invariable disappearance of yellow fever when this species [*Aedes aegypti*]-and this species alone-is sufficiently controlled, it seems quite certain that in the Americas no other mosquito associated closely with man is vector." These outbreaks of jungle yellow fever presented certain special features. For example, infection appeared in or near to areas where clearing of the forest had been incomplete and was limited to those whose work took them into the fields or near the jungle. Thus the original outbreak was almost exclusively among male adults and existing immunity in the same valley was likewise found to be limited almost entirely to the same population group, whereas in Brazilian towns where transmission of infection was through *Aedes aegypti*, immunity was more frequent and more uniformly distributed throughout all age-groups of both sexes. The demonstration of naturally acquired immunity in wild monkeys suggests the possibility of animal reservoirs from which man may derive his infection. But so far the origin and mode of transmission of jungle yellow fever have not been determined precisely. As Soper<sup>2</sup> wrote in 1936 "We have been forced to stand by and observe active jungle outbreaks during the past year with the same sense of futility which must have oppressed our predecessors in regard to urban yellow fever before the discovery of the transmission of yellow

fever by the *Aedes aegypti* mosquito." The experiments of Antunes and Whitman<sup>3</sup> with forest culicidae of the genus *haemagogus* are therefore of interest. These mosquitos attack man with avidity, on several occasions have been seen entering native houses near the edge of the forest, and have been captured feeding on the inhabitants, they have also been shown capable of becoming established in the towns. Because of these facts the authors carefully studied the capacity of this genus to transmit yellow fever. Unfortunately it was not possible to keep these mosquitos alive for long in captivity, and although it was clear from injection experiments that they could harbour the yellow fever virus, in only one of six attempts was it possible to transmit the virus by bite. Certain mosquitos require prolonged periods for the development of infectivity by biting, and it is not impossible this applies to some species of *haemagogus*, although they die prematurely in captivity, they may survive in the wild state long enough to be able to transmit the virus by biting. Whether this genus be implicated or not, the unravelling of the problems of jungle yellow fever will be of great scientific interest and practical importance.

### TABULATION OF POST-MORTEM RESULTS

For some years now a method of tabulation of post mortem results has been in progress in South Australia. These results have been published in the *Medical and Scientific Archives of the Adelaide Hospital*. This publication appears once a year and copies are forwarded to the various medical libraries throughout the world, so that the information contained therein is more or less accessible. The system adopted has been the following. At the end of each post-mortem examination a summary of the lesions is given, either in order of importance or in order of sequence. Trivialities are omitted. A number of copies of each summary are then typed and are pasted on cards corresponding to the lesions mentioned in the summary. If, for instance, gall-stones are present or a duodenal ulcer, one copy of the summary will be pasted under each of these lesions. When a thousand necropsies have been tabulated in this way, the results are arranged in order and are then published in the *Archives of the Adelaide Hospital*. This work has been arranged by Professor J. B. Cleland, who is the honorary pathologist at the Adelaide Hospital. Most of the necropsies have been done by him or if not actually done by him they have been carefully revised by him. The results are consequently uniform in type. What can be achieved under the supervision and direction of one person might not, however, be so successful in the hands of a number of different persons whose ideas might not quite agree. Three thousand post-mortem examinations have now been tabulated in this way, and a fourth thousand is nearing completion. Were similar results published from some of the hospitals in Great Britain, important information might be available as to the incidence of disease and the association between different lesions. For instance, in this way the association of cirrhosis of the liver with lenticular degeneration

<sup>1</sup> *Yellow Fever: An Epidemiological and Historical Study of its Place of Origin*, 1931. Williams and Wilkins Company, Baltimore.  
<sup>2</sup> *Quart. Bull. Hlth. Org. L. O. N.* 1936 5 19.

<sup>3</sup> *Amer. J. trop. Med.* 1937, 17, 825.

might have been revealed if Kinner Wilson had not already recognized this association. Fibrosis of Lungs has a heading to itself apart from silicosis and organized pneumonic exudates. Seven cases all in men appear under this heading in the records of the third thousand necropsies and three of these each had one atrophied testis. Thus the finding of a shrunken testis in a patient with some obscure condition in the lungs would suggest the possibility of this being a diffuse fibrosis. The frequency of a syphilitic history in fibrosis of the testis is well known. The information thus published is available to anyone who is seeking data as to the prevalence of pathological lesions present at death with the sexes and ages of such persons and the association of other lesions.

### PHENOMENON OF REFLECTION

The puzzling phenomenon of reflection was first described by Professor Fridericia in 1926: briefly it is the ability observed in a certain proportion of rats to develop the capacity to grow normally on a vitamin B free diet. This acclimatization may last for a long while so that affected rats can reproduce. But sooner or later it generally disappears and the rat dies with the usual symptoms of vitamin B deficiency. Reflection is accompanied by the passage of pale bulky stools and these have been shown to contain vitamin B<sub>1</sub>. For some time the explanation given of the phenomenon was that conditions developed in the intestines of certain rats which enabled a micro organism to flourish and synthesize vitamin B<sub>1</sub>. It has been satisfactorily demonstrated that certain bacteria have the capacity to synthesize the vitamin but the actual organism responsible for the phenomenon in rats has not been identified. Nathan<sup>1</sup> working in the laboratory of Professor Fridericia at Copenhagen believes that it is probably a Gram negative vibron. Reflection was originally described in rats on a diet consisting largely of rice starch but it has since been shown that potato starch is a better substrate. Nathan has demonstrated that faeces of "reflected" rats contain a large percentage of undigested starch and that the digestibility of this starch by the amylase of saliva is much decreased. He has also shown that although the reflected rats have large quantities of starch in their stools the actual amount of carbohydrate assimilated is no less than in the non reflected rats on the same diet. This eliminates one alternative interpretation which had been proposed—namely that reflected rats assimilated much less carbohydrate than non reflected rats and that their requirement for vitamin B<sub>1</sub> was therefore much less. From these observations he concludes that the cause of reflection is an amylodyspepsia resulting in an environment in the caecum favourable to the growth of bacteria which synthesize vitamin B<sub>1</sub> and therefore supply the animal with what is lacking in the diet. The favourable environment appears to be a high percentage of undigested starch. So far the interpretation appears to be satisfactory but Harris<sup>2</sup> has recently described reflection in rats on bread diets and actually found that

it occurred more easily on a bread diet than on a diet of the flour from which the bread was made. All previous observations had shown that reflection did not happen if the starch in the diet had been cooked or heated. The last word has evidently not yet been said upon the subject. So far no clinical examples of reflection have been described and it would naturally be difficult to do so. Nathan points out that amyloid dyspepsia is not uncommon clinically particularly in children.

### CHRYSOTHERAPY IN PULMONARY TUBERCULOSIS

Little progress has been made in recent years in standardizing the details of administration of gold preparations in the treatment of pulmonary tuberculosis or in determining their efficacy because of the difficulty of obtaining reliable statistical evidence based on comparable groups of patients. In two papers just published on evidence stated to be irrefutable dogmatic claims are made that chrysamine has a favourable influence on the course of pulmonary tuberculosis so that it should be administered in small weekly doses—the maximum being 0.1 gramme—up to a total of 3 to 4 grammes over a period of seven to ten months and that its administration should be stopped on the slightest evidence of intolerance. Courmont, Gardere and Rivollier<sup>1</sup> gave chrysamine only to patients whose condition remained stationary after routine sanatorium treatment. Cases which were hyperacute or too extensive were thought to be unsuitable as were those presenting the well known contraindications—renal, hepatic or intestinal disease. The patients were all males and thirty four of them (Group 1) received a complete course. The administration of gold was stopped in all patients who appeared to be getting worse and in those who developed any accident attributable to the gold. In twenty nine patients (Group 2) it was necessary after 0.1 to 0.5 gramme of chrysamine had been given. In fifty four other patients (Group 3) there appeared to the authors to be no indication for gold therapy. They regard the results of these groups as statistically comparable and have tabulated in percentages thus:

	Group 1	Group 2	Group 3
Disappearance of tuberculous	40%	75%	—
Complete clinical cure	5%	6%	6%
Mild symptoms	52%	25%	—
Intolerance	6%	7%	—
Survivors (improved or cured)	51%	41%	6%

\* Mild symptoms attributable to the chrysamine occurred in 41.1 per cent of the patients and included about six times rashes or localized dermatitis, eight times diarrhoea, six times stomatitis, twice prostration, two weight five times haematemesis, once and profuse haematuria once. Since no patient developed nephritis

<sup>1</sup> Acta path. microbiol. scand. 1937, 14, 43.  
<sup>2</sup> Biochem. J. 1937, 31, 799.

hepatitis, purpura, or severe stomatitis or dermatitis, the authors conclude that small doses prevent serious complications. They believe that the slightest "accident" indicates an unfavourable prognosis and calls for immediate cessation of the administration of gold. In a second paper Courmont and Gardere<sup>2</sup> discuss at length, but unconvincingly, their experimental work on the action of gold and on the causation of symptoms during its therapeutic use.

### FOULING OF THE ATMOSPHERE

The eighth annual report of the National Smoke Abatement Society records the removal of the Society's headquarters from Manchester to London, where offices have been secured at Chandos House, Buckingham Gate, Westminster. The claim is made that the smoke abatement movement has had a real effect in diminishing atmospheric pollution during the last twenty years. Reviewing a longer period, dating from 1881, it appears that since that time the percentage of winter sunshine in London compared with that at Kew has risen from 20 to 55. The report alludes with satisfaction to the increasing interest shown in this important question by Government departments, citing the Report of the Commissioner for the Special Areas, which stressed the desirability of using Welsh or other smokeless coal or fuel in open hearths. Inspectors of alkali works are now directly in touch with smoke abatement matters, and it has been arranged that they should advise the Minister of Health on developments. The total amount of subscriptions and donations to the society for the year under review is again only a little over a thousand pounds, an insignificant figure in view of the scope and importance of the Society's work. Medical practitioners in urban or industrial areas suffer more severely than most classes of the community from the incidence of fogs through the dislocation of their transport, the burden of a heavy increase in the number of cases of respiratory diseases on their visiting lists and the greater risk to their own health. It is to their direct interest to support the society for they will derive special benefit from the results of its activities.

The latest figures of atmospheric pollution show a tendency in the right direction according to the twenty-third annual report on the investigation of atmospheric pollution, just issued by the Department of Scientific and Industrial Research (H M Stationery Office 7s 6d). The report contains a warning however that while a definite improvement in the condition of our atmosphere may be beginning, no far-reaching conclusions should be drawn. Compared with the figures for the general average for the five years ended 1932 which is taken as a basis of comparison in this report, fewer observing stations than last year show a marked reduction in tar deposit. On the other hand fewer stations show an increase. There is an indication of improvement however, in the deposits of fine particles of fuel escaping up the chimney and organic dust of various kinds. Ash deposits also show an improvement and there is a

reduction in sulphate deposits. This latter is of importance in view of the damage caused by sulphur compounds to buildings and vegetation.

### ARCHIVES OF DISEASE IN CHILDHOOD

The first issue of the *Archives of Disease in Childhood* for this year has just been published by the British Medical Association in a revised format. Like this *Journal*, it is now printed in Times New Roman type: the general result is pleasing to the eye and the now familiar type face should encourage new readers to acquaint themselves with what is happening in the world of pediatrics. The editors of the journal are to be congratulated on producing a most interesting and stimulating number, and on the excellence of the illustrations. The first article is by Dr George Graham and Dr W G Oakley, on "The Treatment of Renal Rickets," in which they describe the results obtained in two cases by administering alkali and large doses of vitamins A and D with considerable improvement. This is followed by articles by Dr C Wilfred Vining on "A Case of Periarteritis Nodosa", by Dr Margaret Harper, on "Congenital Steatorrhoea due to Pancreatic Defect", by Dr Alan Moncrieff, on "The Administration of Thyroid Gland to Premature Babies", by Dr D H Paterson and Dr C Hardwick, on "Undulant Fever in Children" by Dr Theodore Crawford, on "A Standard Intravenous Glucose Tolerance Test", and, to conclude, there are case reports on "Paraplegia and Mongolism in Twins" by Dr R G Gordon and Dr J A Fraser Roberts and on "A Foreign Body in the Kidney," by Dr Norman B Capon.

### THE HASTINGS LECTURE

The Sir Charles Hastings Lecture for 1938 will be delivered, under the auspices of the British Medical Association, by Dr H Crichton-Miller in the Great Hall of B M A House Tavistock Square, W C, on Thursday April 7 at 8 p.m. His subject is "Mental Health as a National Problem". The chair will be taken by Mr Ernest Bevin, general secretary of the Transport and General Workers Union. Relevant questions, in writing are invited at the close of the lecture. Admission is free by ticket obtainable from the secretary of the British Medical Association. The doors will open at 7.30 p.m. and seats not occupied by ticket holders by 7.50 p.m. will be available for others.

The *Canadian Medical Association Journal* for March gives preliminary information about the sixty-ninth Annual Meeting of the Canadian Medical Association to be held at Halifax, June 20 to 24 conjointly with the Nova Scotia Medical Society. The presidential address will be given by Dr T H Leggett of Ottawa and the Osler Lecture on "Osler the Last Phase and His Influence on Medicine" by Sir Humphry Rolleston. Drs M R MacCharles of Winnipeg and William Boyd of Toronto will conduct a surgical clinic on cancer. Dr J C Meakins of Montreal a medical clinic, and there will be a symposium on poliomyelitis.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## CONCUSSION AND COMPRESSION

By

LAMBERT ROGERS M.Sc. F.R.C.S., F.R.C.S. Ed.,  
F.R.A.C.S., F.A.C.S.

In the article published last week at page 685 attention was directed to the damage caused by violence to the scalp and the skull but while these lesions may in themselves be very important and have far reaching consequences stress must be laid upon the fact that one of the foremost considerations in all head injuries must be the condition of the brain itself. Our treatment must have as its object not only the preservation of the life of the patient but his protection from untoward after-effects of cerebral injury in the form of headaches, fits, impaired concentration, and other unpleasant sequelae. Increase in motor traffic has caused a corresponding increase in the number of head injuries and the majority of these are of such a character that some damage to the brain is produced. It is important for us to visualize the nature of this damage, the way in which the brain reacts to it and the processes involved in recovery when such takes place.

When confronted with a patient who has been rendered unconscious by a head injury we have to decide on three points: (1) whether he has merely been concussed or whether the brain has been extensively damaged; (2) whether surgical intervention is called for immediately or if the condition is such as not to permit this at the moment whether operation is likely to be required at a later stage; and (3) how we are to manage the case in order to prevent subsequent interference with cerebral function.

### Cerebral Concussion

Professor Wilfred Trotter (1924) has defined concussion as "an essentially transient state due to head injury which is of instantaneous onset, manifests widespread symptoms of a purely paralytic kind, does not as such comprise any evidence of structural cerebral injury, and is always followed by amnesia for the actual moment of the accident." Avoiding discussion relating to the nature of cerebral concussion except to state that it is probably of vascular origin and in the nature of an acute and unsustained compressive anaemia, one need only say that this definition accurately describes the condition which is of everyday occurrence and that it is well supported by clinical experience. From the definition it will be apparent that the subject of a head injury who is unconscious for half an hour or longer is not suffering from concussion. In such cases we must postulate cerebral damage such as contusion or laceration. It also follows that the patient who can accurately relate the details of the accident and remembers the precise impact which caused his head injury has not been concussed and the medico-legal significance of this will be obvious.

It would appear that there is a latent interval in the registration of cerebral impressions and that a sudden interference with the registering mechanism such as is conceivably produced by a severe head injury, cuts off impressions which have been streaming into the brain for some time beforehand. Thus the cyclist who is concussed may remember riding along a road and seeing a motor-car coming round a corner and then all is cut off

until he finds himself being attended to on the roadside. This period of amnesia appears to be a kindly provision on the part of Nature since severe psychic shock might ensue if the precise details of the accident were to remain clear in the mind of the person who was injured. The period of amnesia which is characteristic of both concussion and gross damage to the brain must be regarded as a great saving factor.

### Contusion and Laceration

The next group of cases we have to consider consists of those patients who following a head injury are unconscious for a variable interval, the unconsciousness may last for minutes, hours or days or it may even be of weeks' duration. In these cases there is gross cerebral damage, the brain being extensively bruised and possibly lacerated as well. Bleeding into the cerebrospinal fluid may be shown by its intimate admixture with blood when obtained by lumbar puncture. From the very first also there may be evidence of local damage to the brain in the form of focal signs such as a monoplegia, hemiplegia or ophthalmoplegia.

It is important to examine the nervous system soon after the accident as possible because focal signs then present have been produced by primary injury of the brain. These signs have a different significance from those which appear later while the case is under treatment when they may arise through compression of the brain by oedema or by blood clot, and may call for relief by decompression. There is much to be said for the American practice of having medical officers on ambulances because apart altogether from the importance of first aid treatment particularly in cases of haemorrhage and in facial and other injuries, an early expert examination in a case of head injury is of value in determining the subsequent management of the case.

### Surgical Intervention

**Indications for Immediate Operation.**—Compound fractures of the vault of the skull, if compound fractures elsewhere in the body, require urgent surgery to protect the patient from infection (see article in last week's issue). With this great exception very few cases of head injury require immediate operation. At this early stage operation is practically never required to deal with intracranial haemorrhage—not because haemorrhage does not occur in these early phases of head injury, but because when it occurs they are rapid widespread and associated with extensive damage to the brain and are so quickly fatal as to be beyond the art of surgery even if this be at once available.

**Indications for Delayed Operation.**—In some degrees of fractures elevation should be undertaken when the patient's condition permits and only after adequate preparation. The indications for operation during the course of treatment are discussed later.

### Management of Cases of Brain Injury

After examining the patient to ascertain whether there is a scalp wound, depressed fracture or clinical evidence of a fracture of the base of the skull (see previous article) we should note whether there are any signs of local damage to the brain such as focal or limb palsies or ophthalmoplegia.

plegia The significance of such signs at this stage has already been discussed They must be regarded as the result of local damage produced by the injury, and constitute as it were the primary or basal clinical picture, for changes in which we must be on the alert

The patient is put to bed in quiet and darkened surroundings, with the head elevated to reduce intracranial venous congestion, and fluids by the mouth are allowed in only very limited amounts or are withheld altogether He is given six ounces of magnesium sulphate solution (30 per cent) by the rectal route The solution must be slowly and gently introduced and its administration continued regularly at six-hourly intervals The reason for this dehydration (by withholding fluids by the mouth and giving rectal magnesium sulphate) is gradually but persistently to reduce the quantity of cerebrospinal fluid within the skull and so give the bruised and torn brain space in which to expand as it reacts to the injury The watery fluid is incompressible, and so only by its withdrawal or by the opening of the skull can the necessary room for this expansion be obtained If the damaged brain is allowed to swell and expand the chances of its recovery are very much greater We obtain evidence of this when we compare the reaction to injury shown by organs such as the kidney and the testis If the kidney is bruised it swells (its capsule being readily distensible) and although there may be haematuria for a time the organ gradually returns to its normal size and function The testis, on the other hand, is prevented from swelling because of the inelastic tunica albuginea, which in this sense resembles the cranium, and following a blow such as a kick there is subsequent shrinkage and withering up of the organ, the parenchyma of which undergoes a pressure atrophy because of the restraining and strangling influence of the inexpandable capsule So it is with the brain if we carry out persistent dehydration we both check the inevitable reactionary oedema and permit the injured brain to swell within the skull and make such a recovery of function that the patient is free from unpleasant after-effects This dehydration treatment must be continued for at least ten days and longer in severe cases (for example in a case where the patient was unconscious for three weeks it was maintained for over a month), and may then be gradually replaced by giving by the mouth each morning doses of from one to four drachms of sodium sulphate while continuing to limit fluid intake

**Restlessness**—Traumatic delirium or cerebral irritation is sometimes a distressing feature of head injuries and is probably the result of frontal polar contusion and widespread oedema Since instituting routine dehydration however I have seen it less often and in a less intense form The best drugs for the restlessness are the bromides chloral and its allies such as chloralamide (20 grains twice daily) and hyoscine (1/100 grain) given hypodermically In most cases of brain injury morphine is better avoided because of its depressive effect upon respiration The gently continued dehydration must be persevered with even if the restlessness of the patient makes it difficult

**Lumbar Puncture**—As a routine this is neither necessary nor advisable It is occasionally useful in indicating the state of the intracranial pressure and in showing whether bleeding into the subarachnoid spaces has occurred As a means of withdrawing fluid from the skull and reducing the intracranial tension it is too drastic and the sudden pressure readjustments made upon the damaged brain are probably harmful It should therefore not replace the gradual and continued dehydration treatment already advocated As a means of ridding the cerebrospinal fluid

pathways of blood which tends to set up reactions in the leptomeninges it may be practised with advantage every two to three days in those cases in which the cerebrospinal fluid is intimately mixed with blood Not more than 15 c cm should be removed at a time, and this only slowly—that is with the patient's head low, and through a needle of small bore

### Operation during Treatment Course

If dehydration has been steadily carried out reactionary oedema, should it occur at all, will be minimal in amount and in its effects, and if focal signs arise during the course of the dehydration treatment we must infer that these are due to clot compression—that is a steadily accumulating intracranial haemorrhage It is therefore very important to obtain a neurological clinical picture at the earliest possible moment, and, as previously pointed out, this forms a basal clinical pattern A monoplegia which is present immediately after a head injury must be regarded as due to damage in the motor area of the cortex or along the course of the pyramidal fibres caused by the initial tearing or bruising of the brain On the other hand, a monoplegia arising during the course of dehydration treatment is due to accumulating haemorrhage and usually gradually increases in degree and extent, so that before long it becomes a hemiplegia Such a focal sign of compression appearing in these circumstances is an indication for craniotomy to evacuate the clot and relieve the pressure These signs of local compression which arise subsequently to the primary injury have been aptly termed epiphenomena by Geoffrey Jefferson (1933)

### Traumatic Intracranial Haemorrhage

Intracranial haemorrhage following head injury may occur either within or outside the meninges, and very occasionally takes place within the substance of the brain itself The clinical features are those of focal or general compression of the brain—for example, the presence of paralytic phenomena (a monoplegia becoming a hemiplegia) slowing of the pulse rate or the onset of stupor which may deepen into coma Respiratory failure may occur, particularly if the haemorrhage is in the posterior fossa and the heart may continue beating after respiration has ceased In such circumstances artificial respiration and an emergency posterior fossa decompression are indicated (Rogers, 1933)

Operation in intracranial haemorrhage is done to relieve the brain of the ill-effects of the steady accumulation of blood clot When signs of compression appear craniotomy must not be delayed and efforts to determine the site of the clot compression must be made The site of compression is frequently revealed by the presence of contralateral weakness or paralysis of an arm or leg or of both limbs or by a paralysed pupil on the same side as the clot Progressive drowsiness in such cases is a warning that craniotomy is needed because if the patient is allowed to sink into coma from clot compression the results of operation are not nearly so good as if this is performed when the patient is still conscious or merely drowsy The classical signs of middle meningeal haemorrhage—namely unconsciousness following a blow, a period of return of consciousness (the lucid interval) drowsiness and loss of consciousness again—are by no means always present but this form of intracranial haemorrhage will not be overlooked if when managing the case along the lines here laid down we are on the alert for signs of compression We must be on the watch for epiphenomena

## Treatment of Intracranial Haemorrhage

Details of operative treatment are beyond the scope of this article. Blood clot may be removed through burr or trephine openings or through an osteoplastic flap cut for this purpose. If burr openings are used several may be necessary and small scoops for removing clot and a stream of hot saline are useful accessories.

## Illustrative Cases

The following cases illustrate the application of the principles of treatment which have been considered.

**Case 1**—A farm labourer aged 37 was admitted to hospital semiconscious and restless. In a brawl he had received a blow over the left temple from a part of a steel plough. While he was undergoing dehydration treatment cerebral irritation was a prominent feature. Three days after admission while still semiconscious he developed a right monoplegia which soon progressed to a hemiplegia. Intracranial haemorrhage was diagnosed and a left osteoplastic craniotomy carried out. A large amount of extradural blood clot (185 grammes) from a ruptured middle meningeal artery was removed and the bone flap replaced. He made a complete recovery.

**Case 2**—A schoolboy aged 12 when playing at school one morning was struck over the left parietal bone by a small stone which had been thrown by another boy. He was only slightly dazed and did not lose consciousness. That night he had a headache but was otherwise well. During the following week his parents noticed that he was becoming more and more drowsy and five days after he had been struck he was semicomatose. He was seen by his doctor who sent him to hospital. Craniotomy was performed at the site of the blow and outside the dura mater a large mass of blood-clot from a torn middle meningeal artery was found and removed. He regained consciousness shortly afterwards and recovered completely.

**Case 3**—A contractor aged 32 received a blow on the head during a fight. He walked to his home. The next morning he suffered from headache and vomited. A week later because of persistent headache he was sent to hospital by his doctor. A lumbar puncture revealed lemon coloured cerebrospinal fluid the pressure of which was normal. He was kept in bed and placed on dehydration treatment but was inclined to be anxious and irritable. Fifteen days after his admission he became drowsy and developed left hemiplegia and examination showed choking of both optic disks. During the day he steadily became more drowsy. Intracranial haemorrhage probably subdural was diagnosed and operation was performed forthwith. The dura was tense and bluish and when opened a large collection of old blood clot was revealed. This was removed and the subdural space washed out with saline. He made a complete recovery.

**Case 4**—A consulting physician aged 53 who had sustained a head injury in a motor accident was admitted to hospital comatose and cyanosed with stertorous breathing and a right monoplegia. He remained unconscious for three weeks. His cerebrospinal fluid was intimately mixed with blood and a diagnosis was made of extensive cerebral contusion and laceration. A ray examination showed a fracture through the squamous temporal bone of the right side running into the base. He was given the dehydration treatment to which reference has been made and was kept quietly in bed. Although in consultation craniotomy was urged by colleagues because of the focal sign (monoplegia) it was not carried out since it was concluded that as the sign had been present from the first it was caused by the primary contusion. He remained unconscious for three weeks but made a complete recovery and is now back in consulting practice. There were no indications of an accumulating intracranial haemorrhage in this case. Dehydration was all that was necessary.

## INTERNATIONAL CONGRESS ON RHEUMATISM AND HYDROLOGY

## OPENING OF OXFORD MEETING

The International Congress on Rheumatism and Hydrology was held at Oxford from March 28 to 30 and is being followed by the International Congress on Rheumatic Diseases at Bath from March 31 to April 3. The Oxford meeting which was the fifteenth anniversary of the International Society of Medical Hydrology and the tenth of the International League against Rheumatism was attended by about 200 representatives. Only one of the several delegates expected from Austria was present and none from Czechoslovakia and other countries in Central Europe and it was stated that an announced delegate from Soviet Russia was a political prisoner. But German and French were heard as frequent as English in the discussions. The first words uttered indeed were in German when at the ceremonial opening at the Sheldonian Theatre Professor H. VOGT of Berlin proposed the election of Sir Farquhar Buzzard as President.

## President's Address

SIR FARQUHAR BUZZARD devoted much of his brief address to describing the part played by Oxford men in promoting the study of hydrology. His first example was Dr Walter Bailey of New College Regius Professor of Medicine who in 1587 described the medical properties of the springs of Worcestershire. After congratulating the editorial committee responsible for the volume entitled *A Survey of Chronic Rheumatic Diseases* published in commemoration of the bicentenary of the Bath Royal National Hospital which he said was a challenge to the medical profession to spend yet more of its time and energy in attempting to overcome some of the most distressing and disabling scourges of all civilized race Sir Farquhar Buzzard continued.

The problem is one—and there are several others in medicine—in which the clinician the pathologist the bacteriologist and the biochemist need all the help and information they can obtain from the student of preventive and industrial medicine from the statistician and from the social worker. Some help from all these sources is already available but insufficient attempts have as yet been made to correlate the contributions and control the results with scientific accuracy. Is it too much to hope that sufficient money might be forthcoming from Government or other sources to establish centres for the studies where the social worker the statistician the clinician and the pathologist might work together under the guidance of experts in preventive medicine and social hygiene?

He also touched on the timely significance of the fact that experts were present from Germany France Belgium and other countries conferring in an atmosphere of earnest friendliness seeking only truth and assured of good will and understanding. Would that matters of far less importance than health could be discussed in a similar spirit.

## Climate in the Causation of Disease

The first discussion held at the University Museum was on Wet and dry climates and weather in the causation of disease. Dr E. P. POULTON of Guy's Hospital in an opening paper said that he had found that to plot absolute humidity against temperature provided a measure of climate which was easier to assess than the more complicated relative humidity. On this basis he had plotted average monthly values for humidity against temperature and he showed curves for Calcutta and other places in India and for Kew and various meteorological stations in Great Britain. Each station had its characteristic curve and could be classified into types according to geographical influences. A hot summer day in England

was always humid. Mountain climates had low humidities and low temperatures. Complaint said Dr Poulton was often made of the variable climate of the British Isles. The average monthly figures, however, showed a dull uniformity when compared with possibilities in other countries, but probably it was the day-to-day changes which counted for most in the feelings of the patient, and these were not shown by the average monthly figures.

While rainfall in this country had but a small effect on the average monthly figures for temperature and humidity it was only necessary to look at the daily weather report to see that a shower of rain had usually an immediate effect almost completely saturating the air with moisture, or the high saturation might precede the shower. Although the lessening of evaporation by the skin, with perhaps added circulatory changes, would not be enough to produce general effects, it might quite well cause local disturbances in parts already inflamed, such as subcutaneous tissues, fasciae, and joints, which were well known in rheumatic patients to be sensitive indicators of damp associated with cold. But one of his patients had informed him that hot weather also caused pain, and that was not an unfamiliar experience.

During the last two years he had been struck by the possibility that dryness of climate was an agent against pulmonary tuberculosis. Open-air and mountain treatment of this disease might depend on atmospheric dryness. He pointed to the serious tuberculosis problem in India with its high humidities in all but certain of the hill stations. In the open-air treatment of phthisis in this country dryness of the air might perhaps be a factor. He had thus been led to try the effect of artificially dry air in the treatment of tuberculous patients. The patient lay in a bed tent kept at room temperature by ice. The Guy's model oxygen tent was used and supplied with air passed over silica gel. It was too early as yet to quote clinical results.

#### Effect of Variability of Climate

Professor GUNNAR EDSTROM of Lund, Sweden, followed with some interesting observations on the good and evil effects of a variable climate. Such a climate was trying to the organism, but it kept it in better trim and vigour. It created a heavy incidence of disease in many areas, but on the other hand it promoted longevity. In the United States the three regions marked by greatest variability of climate had the highest frequency of valvular disease of the heart, endocarditis, diabetes mellitus, and functional psychosis. On the other hand, in the same areas there were the greatest number of old people and the lowest number of mental defectives. In Europe the highest proportion of people above 80 years of age was to be found in Sweden, Norway, Eire, and the Faroe Islands, countries which had the most variable and biologically oppressive climate. The countries bordering the North Sea with their variable climate, also exhibited, on the whole, the highest frequency of rheumatic diseases in Europe, and here valvular disease of the heart and endocarditis attained their greatest incidence. The speaker showed many charts illustrating the conditions in his own country of Sweden and brought out the parallelism between the high percentage frequency of rheumatic fever among medical admissions to hospitals in districts where the climate was unstable and the high percentage frequency in these same districts of great longevity. No parallelism between these conditions and absolute or relative humidity of air, rainfall, or cloudiness could be discovered. A wet or dry climate solely as such had no significance with regard to the frequency of rheumatic fever; the feature of greatest importance was climatic lability, abundance of cyclones and anticyclones, it was the weather changes that produced the biological effects.

#### "Change of Weather" as an Exciting Cause

Professor DE RUDDER of Berlin also discussed the effect of alternations of cyclones and anticyclones as an exciting

factor in various disorders. Where the relation between the weather conditions and the incidence of disease was not observable beyond all ambiguity, a true and not adventitious coincidence could often be established by the keeping of statistical records. He gave a table of the groups of disorders more or less clearly shown to be 'meteorotropic' in character—that is to be excited or worsened by what is commonly described as "change of weather," but which he called "lines of aerosol interface between weather systems or air masses of different kinds." He pointed out that many of the methods in use in physical medicine generally and in medical hydrology in particular were directed towards reducing this peculiar sensitivity.

An investigation into the muscular irritability of forty-three working people day by day over a period of six months with special reference to change of weather, was described by Dr ODON SCHULHOF of Budapest. He had estimated the reactions of these persons to small electrical current intensities, and showed the characteristic curves with fluctuations corresponding to warm and cold periods. Dr TRAUNER of Belgrade gave a description of the incidence, varieties, and treatment of rheumatic conditions in Yugoslavia, with special reference to climate, and representatives of France and Belgium continued the discussion.

#### Juvenile Rheumatism

The subject of juvenile rheumatism was discussed, in successive sessions, from the pathological, clinical, therapeutic, and social aspects. In introducing the subject Dr A. G. GIBSON of Oxford said that juvenile rheumatism in its typical features with carditis was only seen in the young; it was a disease of school age. The peak incidence was 7–10 years in London. It was associated with damp, was prevalent in some families, and in its incidence it followed acute infections, especially those due to the streptococcus. The primary streptococcal infection was most commonly in the upper respiratory tract. Many workers had shown the intimate relation of some form of streptococcus in cases of rheumatism to several different lesions, such as pericarditis, arthritis, and even chorea, but the large number of negative findings threw doubt on the observations. Treatment by streptococcal vaccines, protein shock, and intravenous flavine seemed to produce no great benefit, though anti-streptococcal serum had been used with good results. Professor F. KLINGE of Germany said that rheumatic fever (acute polyarthritis) in children as in people of later years, was a generalized disease, but attacking principally the locomotor apparatus and the internal organs. A progressive form of rheumatic disease typical in the early years of life was visceral rheumatism, characterized by serious and widespread tissue damage to the internal organs without affecting the organs of locomotion. Its great medical importance derived from the fact that it brought about acute, subacute, and relapsing disorders of the heart and blood vessels.

#### Clinical Aspects of Rheumatic Infection

The clinical aspect was opened by Dr LEONARD FINDLAY who said that no definite statement could be made regarding the manifestations of rheumatic infection until the true cause was discovered and some specific test made available. Hence the search for the aetiological factor was a matter of primary importance in the further study of the disease which, in the first instance, it seemed wise to limit to those manifestations about which there was general agreement and probability of relationship. At present the only conditions which could be accepted as probable manifestations of rheumatic infection were in order of importance arthritis, carditis, chorea, the subcutaneous nodule, and erythema circinata, but not one of these conditions was pathognomonic of the disease and each of them could be and was with varying frequency caused by some other infection. The diagnosis of the rheumatic infection depended on the combination and association of various manifestations.

Certain other manifestations from time to time ascribed to the rheumatic person such as inflammations of the pleura, meninges, peritonaeum and lungs were in Dr Findlay's opinion not justifiably to be considered as rheumatic in nature, but the ultimate decision must wait the discovery of the cause and the development of some specific test. The subject was also opened by Dr H. GRENET of Paris whose paper covered almost the entire field from aetiology to prognosis. Statistics of his own cases showed that 72 per cent of rheumatic children had at some stage a heart lesion. This always occurred after either the first or the second attack and in 65 per cent the damage was permanent. He insisted on the gravity of the cardiac condition and out of 184 cases recorded in the last ten years reported forty-four deaths. He admitted no analogy in kind between the slow malignant endocarditis and the progressive rheumatic carditis. The prognosis of juvenile rheumatism was generally unfavourable. Among all cases observed in hospital over ten years the total mortality was 17.39 per cent.

The discussion on juvenile rheumatism which occupied two days and for which over thirty speakers were on the programme will be more fully reported in the next issue. Between sessions the delegates managed to see something of Oxford and its environs and the hospitality of the University was extended at a reception given by the Vice-Chancellor at the Ashmolean Museum on Tuesday evening. On the Saturday preceding the Congress the Royal College of Physicians of London gave an evening reception.

## Nova et Vetera

### WHAT DID BALZAC DIE OF?

J. G. E. Guerin has devoted his inaugural thesis (*Thèse de Paris* 1938 No 57) to an interesting inquiry as to the nature of the disease which carried off the great French novelist Honoré de Balzac at the relatively early age of 50. His father and mother died at 82 and 76 respectively and he would therefore have seemed likely to enjoy a long life. There is no history of his having had any severe illness in childhood or early life and his contemporaries described him as the picture of health and gaiety.

During his period of literary activity Balzac observed a special mode of life. He slept only five or six hours, ate very little chiefly fruit, drank very strong coffee and a little Vouvray wine and took a bath daily of an hour's duration. Although there is no doubt that he was overworked and took too much coffee these factors are not sufficient to have caused his early death. After 1832 when Balzac was 33 years of age his correspondence shows that he suffered frequently from headache and vertigo and it was obvious that his principal symptom was hypertension. As regards the cause of this hypertension although overwork, excess of coffee and plethora in a subject inclined to obesity as Balzac was were important factors they were not enough to give rise to severe hypertension in a relatively young and vigorous man. A few years before death he developed symptoms of dilatation of the aorta which in the absence of a history of infective endocarditis or acute rheumatism can only be attributed to syphilis. The cerebral excitement associated with his prodigious literary activity and the arterial involvement were responsible for Balzac's premature death. The aortitis gave rise to hypertrophy of the heart and the subsequent cardiac failure was accompanied by pulmonary symptoms such as dyspnoea and acute oedema of the lung, congestion of the liver, oedema of the lower limbs and albuminuria.

## Reports of Societies

### PHYSICAL EDUCATION

At a meeting of the Section of Physical Medicine of the Royal Society of Medicine on March 18 with Dr F. D. HOWITT in the chair a discussion on physical education was opened by Viscount Dawson of Penn. The full text of whose address appears at page 734.

#### Physical Education in Europe

Professor B. A. McSWINEY described a tour which he had undertaken at the invitation of the Health Committee of the League of Nations of certain European countries to ascertain international co-operation would assist the development of this subject. The countries visited included Denmark, Sweden, Holland, France, Italy, Austria, Czechoslovakia, Poland (one of the most interesting institutes of physical training was centred at Warsaw) and Germany. The outlook was widely different in many of these countries. In Denmark, for example, the object was to encourage uniform bodily development of the child. In Italy it was to reorganize the State on a new basis. In most European countries games at present did not form an important part of physical education. His opinion and that of his colleagues who accompanied him was that it would be difficult perhaps almost impossible to establish an international system and indeed such a system might be desirable for the plans which produced excellent results for one type of population were not necessarily suitable for another type. In nearly all the Swedish schools even the small country ones a space had been set aside for gymnasia. In most European countries—Germany was an exception—no special provision had been made for the physical education of boys and girls after leaving school or of adults or unemployed persons unless they were able to join private clubs. It was also observed that in most of the countries scant attention was paid to children who were below normal. Little knowledge seemed to be available as to the effects of physical exercise on the functions of the body. There was scanty co-operation between school medical officers and physical instructors. The latter in many of these European countries had too much responsibility and the danger of physical education being regarded merely as a matter of school routine.

#### Physical Training in the Army

Major W. CAMPBELL, hygiene specialist of the Army Physical Training School at Aldershot, gave an account of that establishment. The appointment of the first whole-time officer at the school was made in 1922. It was realized that the construction of correct, balanced and progressive physical training tables required a knowledge of some of the main principles of anatomy and physiology and that therefore the presence in the school of a specially trained medical officer would be of considerable value to the teaching staff. The function of a hygiene specialist corresponded closely to those of a medical officer of health in civil life and embraced preventive medicine. He took a three months course of physical training for himself which gave him the atmosphere of the school and taught him to sympathize with the men who were doing these things. In addition he did what is called a post-graduate course in the physiology of muscular exercise. He was required in the school to be able to deal with questions arising out of physical training in men who although they were not medically qualified had undergone physical training for years and knew a good deal

of anatomy and physiology. No new exercise was introduced into the tables without a discussion between the medical officer and the teaching staff. Indeed, no exercise could be modified to any degree without such consultation.

The duties of the medical officer were generally the duties of a regimental medical officer, such advisory duties as he had indicated, the giving of instruction the performance of routine observations and tests, and research. It was the policy of the school to base physical training on medically sound lines, and therefore considerable importance was attached to the teaching of elementary anatomy and physiology to the students. This knowledge placed the future instructor in a better position to teach his own subject, encourage the backward, and restrain those enthusiasts who would go too fast and too far. Lectures on anatomy and physiology were given by the medical officer. The various systems of the body were taught, with special emphasis on the correlation of the respiratory and cardiovascular systems. He gave an account of the routine tests and observations. The tests were designed not to assess the physical fitness—because it was assumed that these men were physically fit already—but to ensure that they were not unduly fatigued. Researches had been made on the grading of groups of exercises, the effect of smoking on endurance (it had been definitely shown that in the great majority of cases smoking militated against endurance, though there were exceptions), and on rhythmical breathing in accordance with the steps in walking.

SIR ARTHUR MACNALT said that active steps had been taken to set up the national college of physical training. Without trained teachers and leaders the fullest use could not be made of opportunities provided, and one of the functions of the college would be to assist in supplying these teachers. It was also contemplated that the college would investigate some of the many outstanding problems connected with the physiology of this subject. In the mental and physical training of youth it was important that full use should be made of the services of preventive medicine, or zeal for either form of culture might outrun discretion. The Greek aim was a balanced rhythm. Socrates observed that runners often had overdeveloped legs and weak trunks while boxers were too heavy in the upper part of the body.

MR PHILIP WILES commented that the audience had been dragged from Lord Dawson's eloquent description of life at its best to a description of how physical training was being abused in the Fascist countries, where men were trained with the declared objective of destroying their fellow human beings. The developments in Europe should place us on our guard in this country against a similar degradation here. The rapidity with which the Government scheme of physical training was introduced gave rise to certain doubts among the profession, but Lord Dawson had gone a long way to allay them. It was essential that physical training of some sort should come into being but he did not think that any individual should be encouraged to participate unless there was evidence that he was getting enough to eat. In Moscow everybody who participated was required to be examined by a specially trained medical man in order to make sure that he was fit.

SIR ROBERT STANTON WOODS said that it was the inescapable duty of every medical man to afford help in this great effort to the utmost of his capacity and opportunity. He also warned against easy discouragement owing to the nature of early results.

LORD DAWSON said that he was all for studying nutrition side by side with physical training but he hoped there would be no alarmist note on this subject. One had only to watch a gathering of elementary school children to be sure that on the whole they were very well fed. Malnutrition did exist but only in patches, it was not universally spread.

## PAINFUL FEET

At a meeting of the Hunterian Society on March 25 the subject under discussion was "Painful Feet." By way of introduction Dr D. C. NORRIS the President drew attention to two beautifully recorded "case histories" many centuries old. One was the case of ASA (2 Chron. vi), who was "diseased in his feet, yet in his distress he sought not to the Lord, but to the physicians. And ASA slept with his fathers." From the fact that the apothecaries brought into his bed sweet odours and divers kinds of spices it seemed like a case of senile gangrene. The other was the case of Mephibosheth (2 Samuel ix), who "did eat continually at the King's table, and was lame on both his feet."

### Evolutionary Causes

MR NORMAN LAKE said that the foot was a part of the body which was undergoing not evolutionary advancement but evolutionary regression. The feet of the ancestors of the human race must have been capable of a much wider range of movement, being designed to carry out many of the things which man did with his hands. The modern human foot had become a stereotyped structure, apparently restricted to the performance of one simple task. Not only were the feet of modern man encased but in all civilized countries the ground was levelled so that in ordinary progression the foot was never called upon to carry out more than a narrow range of movement. The evolution of the modern foot could be traced to some extent in the various types of gorilla where the great toe became more and more incorporated with the rest of the foot, instead of being as it was originally a separate and opposing structure, like the thumb of the hand. The incorporation of the great toe was, from the evolutionary point of view, a thing of yesterday and anything of recent happening in evolution was likely to be unstable. As the great toe became incorporated so its size increased. In the chimpanzee it fell short of the length of the other toes, in human beings it commonly equalled the second toe. In the anthropoid apes the second and third metatarsal bones were fairly stout, capable of carrying the stress put upon them, while the first was relatively weak, but in man the length of the first metatarsal bone was increased considerably and the leverage axis of the foot had been altered, with consequent redistribution of pressures.

The solution to the problem of many cases of painful feet, which could not be pigeon-holed as hallux valgus or ingrowing toe-nail, or hammer-toe was to be sought in the fact that the foot was not yet entirely suited to the environment thrust upon it. The outlook from the point of view of treatment was not very promising. The aim should be to bring back some of the strain of locomotion on to the first metatarsal, relieving to some extent the second and third. But it was not easy to redistribute strains in the foot. A well-known plan was to fit a metatarsal pad immediately behind the head of the bone raising it out of the position of strain or, conversely, the shoe might be built up underneath the head of the first metatarsal. There was a tendency when confronted with a painful foot for which there was no obvious cause to blame the shoemaker. Mr Lake was not prepared to incriminate the shoe, always excepting the high heeled shoes of women. The real trouble in very many instances was an evolutionary misfit.

### The Chiropodist's Methods

MR J. H. HANBY, Fellow of the Incorporated Society of Chiropodists, gave a demonstration of the way in which felt pads were applied for the equalization or relief of pressure and to bring into alignment such deformed structures as were sufficiently supple and amenable to be so treated. He pointed out that the application of felt to the foot in unskilled hands might do much harm. Great

skill was required in the shaping and tapering of the felt so as to avoid bruising. He showed in particular how the pad was applied to even out the pressure over the five metatarsal bones. He also touched upon the many painful conditions associated with the nails. A large number of thickened malformed nails could be reduced to almost normal by means of an electric nail drill, a painless procedure in the hands of a competent chiropodist and of great benefit to elderly patients by whom operation was not acceptable. Mr Hanby concluded with some remarks on footwear. In his view socks and stockings particularly in children were a very important factor in the welfare or otherwise of the feet. He had examined 300 children at a school and had found 65 per cent of them below the age of six to have signs of some foot trouble in a large number the first stage of hallux valgus. It was not caused by the shoes but in a large number of cases by ill fitting hose. Women also often wore their stockings too short for the reason that if the stockings were long enough they were usually too large around the ankle but the consequence was foot trouble. He warmly supported the remarks in the letter by Dr Margaret Emslie in the *Journal* of March 5 (p 544).

Mr C LAMBRINUDI remarked that his hospital (Guv's) was the first to appoint a chiropodist to work in co-operation with the orthopaedic surgeon. He regarded the assistance of a chiropodist as being as important to the orthopaedic department as that of a masseuse. Indeed they were complementary to each other. Mr Lake had expounded the evolutionary cause of pain but he did not suppose he regarded imperfect evolution as the sole cause. There were other causes of an acquired nature. In his own view the tips of the toes were every bit as important as the metatarsal heads. He entered into a discussion of the function of the toes in walking and the action of the flexor longus hallucis muscle.

Dr J B COOK said that the question of the recognition of chiropodists had again recently received consideration by a committee of the British Medical Association (the Hospitals Committee) of which he was a member. Certain regulations had been drawn up restricting the domain of the chiropodist as a condition on which recognition could be given but after witnessing Mr Hanby's convincing demonstration that evening he felt that some of these regulations were ridiculous—for example the one which required chiropodists to limit their activities to structures no deeper than the true skin. He for his part would do his utmost to further the interests of chiropodists in the future in this matter of recognition and also to get a chiropodist appointed to his own hospital.

#### Other Causes of Painful Feet

Dr FORESTIER mentioned some deeper troubles. He did not think that Morton's metatarsalgia was due to a mechanical fault; it had some cause connected with the circulation. In the hope of discovering the nervous stimulus involved in these obscure pains he had made local injections of lipiodol between the third and fourth metatarsal heads and sometimes between the fourth and fifth and after these injections the trouble had cleared up in a quite remarkable manner. Another cause of pain in the foot was papillomas on the sole. He had found these yield to x-ray treatment.

Mr S L HIGGS mentioned the condition of plantar warts. These very often appeared in a moist and soft skin and might be due to some extent to abnormal pressures. It was rare to find a plantar wart on a dry hard skin. Plantar warts appeared quite commonly in young girls especially the type of girl who was taking rather too much exercise. X-ray treatment was useful but it was important to keep the skin dry and to apply some fungicidal preparation for a short time.

Mr F MCG LOUGHANE said that after all Mr Hanby's treatment for the removal of pain was merely

palliative. Unless the patient was within reach of the expert people who applied and renewed these pads, his case was not permanently benefited and the speaker thought it was for the orthopaedic surgeon to develop operations and exercises which would have a permanent curative value. If the fault was one of anatomy, surgery and physiology could always overcome it.

Mr MORTIMER WOOLF said that his own feeling was that many of the painful feet which one saw were due to overmuch pressure on the first metatarsal bone more especially when the first metatarsal was maintained in a position which was mechanically unfitted to support the pressure. When a child was born its foot was held in a position of varus but from the moment it began to assume the erect attitude its nurse mother and teacher made it turn out its feet at an angle of about 35 degrees. This was a relic of military barbarism dating from the time when armies marching in close formation were required to have the feet at that angle otherwise the men kicked the heels of the row in front. When the toes were turned at that angle the whole weight of the foot came on the sesamoid bones which were apt to become displaced and then the weight came on the head of the first metatarsal. On the other hand athletes had their feet slightly inverted. Relief from foot strain could always be secured by turning the feet in.

Dr P B SPURGIN and Dr ERNEST YOUNG gave some personal experiences with special shapes of shoes which accommodated the natural contour of the foot. Dr GERALD SLOT referred to certain hitherto unmentioned causes of pain in the foot notably sciatica. Very often a sciatica was found in which the pain was referred entirely to the foot. Dr J G JOHNSTONE (consulting orthopaedic surgeon LCC) said that he agreed with Mr Lake's reference to congenital abnormalities but he was surprised that so little had been said as to other causes of painful feet. Many acquired deformities were to be seen. The possibility of an infective focus also should not be disregarded. Mr REGINALD HILTON referred to some work which had been done in Massachusetts upon the barefooted African negro from which it appeared—rather opposing Mr Lake's contention—that few foot deformities were found among these people thus suggesting that footwear was a common cause of foot pain in the shod European.

Dr PHILIP ELLMAN in proposing a vote of thanks to the speakers said that he could add still other causes of painful feet. One not mentioned that evening was the occurrence of obesity more particularly in women at the menopause the foot pain being due probably to disturbance of the body equilibrium. Another interesting cause was unilateral Raynaud's disease and still another coccal rheumatism.

#### INTRACRANIAL HAEMORRHAGE

At a pathological meeting of the Liverpool Medical Institution on March 10 with the president, Dr E GILBERT BARK in the chair, Dr A J McCALL and Dr T W WADSWORTH opened a discussion on intracranial haemorrhage.

Dr McCall said that the principal mechanism of cerebral haemorrhage could be summarized as (1) rupture of an atheromatous artery without previous damage to the brain parenchyma (2) rupture of a vessel passing through the site of an antecedent thrombosis and (3) haemorrhage by diapedesis due to cerebral angioma. Cerebral haemorrhage was usually but not invariably fatal. Subarachnoid haemorrhage commonly followed the rupture of a congenital aneurysm and it was generally agreed that syphilis was rarely responsible. Syphilitic aneurysms however were occasionally encountered in the larger vessels such as the basilar or vertebral arteries. In gummatous meningitis a diffuse oozing of blood might occur from the pial vessels, but was rarely sufficient to cause

a clinically evident subarachnoid haemorrhage Dr Wadsworth analysed cases of intracranial haemorrhage from the last 3 000 necropsies at Walton Hospital. In seventy-six adults a diagnosis of cerebral haemorrhage had been made before death; in forty-five of these cases the diagnosis was confirmed post mortem. There were eighty-eight cases of cerebral thrombosis (forty-eight females and forty males); there were twenty-eight cases of meningeal haemorrhage occurring in the first week of life or in still-born children.

Dr ROBERT KEMP, discussing the aetiology of basal aneurysm, said that the average age at which this condition was seen was in the forties. Cerebral haemorrhage was commonest in the fifties, so that although the basal aneurysm was grafted on a congenital weakness other factors in later life would seem to determine its growth or at any rate its rupture. It was noticeable, too, that bleeding sometimes took place when the patient was at rest or often after the mild exertions of everyday routine. At other times an appreciable haemorrhage was preceded by several days of slow leaking—again suggesting that even though the sac might have been there for some time its actual rupture was determined by a transient and unexplained weakness of its wall. Dr T. F. HEWER, who considered syphilis rarely if ever a cause of subarachnoid haemorrhage, referred to Turnbull's suggestion that although syphilis generally caused an obliterating periarthritis there was a possibility that a very acute syphilitic reaction might be haemorrhagic. He had examined the cerebrospinal fluid in many cases of severe acute syphilitic meningo-encephalitis including some cases of neuro-recurrence after insufficient treatment with arsenicals in African natives but there was never any indication of haemorrhage.

### A PHILOSOPHER ON PSYCHOLOGY

At a meeting of the Medical Society of Individual Psychology on March 10, with Dr H. C. SQUIRES in the chair, Professor JOHN MACMURRAY read a paper entitled, 'A Philosopher's View of Modern Psychology'.

Professor MacMurray began by saying that the function of the philosopher was to relate the field of the expert to the more general field in which it was included. Looking at medical science he noticed that the relation of doctor and patient from which medical science and practice arose was a particular type of relation between persons. It conditioned everything within the held of medicine and was itself conditioned by the nature of human relations in general. The patient was a person who was anxious about himself who asked another person to help him. The fact that the doctor-patient relation was a relation of persons provided certain principles in itself. Just as a teacher who taught his subject and not his pupils was a bad teacher so a doctor who set out to heal diseases instead of people would not be a good doctor. The patient as a person requiring help was the focus of all problems in medicine. If medicine treated diseases then a classification of diseases into bodily and mental would arise in which the unity of the person was lost sight of. Physicians and psychotherapists would have different objects to treat and the necessity for co-operation in treating a patient who was always suffering in mind, whether or not he was suffering organically would be lost sight of.

Every case which a doctor dealt with arose because of the patient's anxiety about himself. His anxiety which brought him to the doctor was his sense that something was the matter with him. The task of the physician was to discover what was the matter. If some mal-functioning of the organism could be discovered then it could be correlated with the anxiety of the patient about himself. If this was correct then the restoration of proper bodily functioning would remove this anxiety and bring the relation of doctor and patient to an end. But if the doctor could assure himself that there was no organic failure

sufficient to account for the anxiety of the patient, what was to be done? The physician might feel inclined to say that there was nothing the matter with him. But there must be something the matter with a man who came to a doctor when there was nothing the matter with him. The anxiety must have a cause. As it was an anxiety about himself the cause must lie in himself. If it had no observable bodily correlate the anxiety itself was a disease, and expressed the patient's sense that something was the matter with his functioning as a human being. The task of finding what was the matter and curing it was then the task of the psychotherapist.

Professor MacMurray devoted the rest of his address to a determination of some of the general characteristics of fear as exhibited in human behaviour. He emphasized the need for distinguishing fear and its derivatives as negative motives with an inhibitory effect from the positive motives which determined the positive life processes. He distinguished human fear from 'animal fear' by the presence of anticipatory fantasy. He pointed out that in all the development of consciousness, and especially in all rational reflection, fear was always present. Reflection itself involved the inhibition of action. In action fear expressed itself as caution, the recognition of the possibility of mistaken behaviour, and so in the distinction between right and wrong. Thus it was a mistake to maintain that fear was neurotic in itself. Nevertheless, anxiety as a pervasive fear which determined an egocentric and self-defensive attitude to life was in expression of human mal-functioning. The rhythm of human life involved both fear to provide the motive for withdrawal into reflection and the triumph over fear to provide the return to positive activity enriched by reflection. This general diagnosis of human mal-functioning he added, could not be complete without reference to love in relation to fear, because of the inherent mutuality or reciprocity between persons which was the characteristic feature of human life. The environment for any person was primarily other persons. For this reason love negated by fear was the all but universal source of neurosis.

Professor MacMurray concluded by saying that these general considerations of the wider situation which conditioned psychological medicine suggested to him that he would expect that in psychotherapeutic practice the nature of the relation established between doctor and patient would play a major part in success or failure and also that the truth of the psychological theory held by the doctor would prove of less importance in the achievement of a cure than might at first sight be expected.

### PROPHYLAXIS OF INFLUENZA

At a meeting of the Pathological Society of Manchester on March 9, with the president, Professor DANIEL DOUGLAS in the chair, Dr WILSON SMITH read a paper on the search for an influenza prophylactic.

Dr Smith said that a virus was first isolated in 1933 by the intranasal inoculation of ferrets with throat washings obtained from cases of influenza, since then many strains had been isolated by a similar technique all over the world. The ferret disease closely resembled human influenza in its symptomatology and the ease with which it was transmitted by contact. The entry of the virus into the respiratory tract was, however, necessary for infection. Virus inoculated by other routes was innocuous. A lung-adapted strain of virus obtained by serial passage under anaesthesia caused a much more severe illness accompanied by pulmonary consolidation. Ferrets which had recovered from influenza were completely immune to reinfection for a few months, then the immunity waned slowly so that for some time experimental inoculation of the virus was followed by a mild disease of short duration without any lung involvement. The resistant state was characterized by the presence of virus neutralizing antibodies in the blood.

The virus was later adapted to mice in which animal it produced a virus pneumonia. By grading the dose of mouse adapted virus it was possible to obtain all degrees of lung involvement from small root lesions to complete consolidation of all lobes. Other ways of propagating the virus were by growth on the chorio-allantoic membrane of the developing chick embryo and by growth in a medium consisting of minced chick embryo and Tyrode's solution. Ferrets, mice and eggs had all been used in the search for a prophylactic. The tests employed to gauge the effect of vaccination upon resistance fell into two main groups—tests in which the animal was exposed to infection and tests designed to measure the antibody level of the animals' serum. Antibodies might be measured by virus neutralization tests in ferrets, mice and eggs or by the *in vitro* complement fixation reaction. Unfortunately the results obtained by these different tests showed puzzling discrepancies with some sera and it was not yet known which test gave the truest measure of active immunity.

### Virus Vaccines

Vaccination of normal ferrets conferred a degree of resistance sufficient to protect against contact infection but insufficient to protect completely against large doses of virus inoculated intranasally. The induced partial immunity however saved the lungs from involvement when the lung adapted strain of virus was used for the immunity test. Vaccination of ferrets which possessed some residual immunity as a legacy from a past attack of influenza restored the solid immunity which they enjoyed immediately after recovery. Vaccination of mice resulted in the complete protection of a high proportion of animals, a reduction of mortality rate and a decrease of the extent of lung involvement in those not completely protected. Experiments with mice had been particularly useful for comparing the efficacies of different vaccines with a view to obtaining the most suitable product for use in man.

Prophylactic experiments in human volunteers had been carried out in England with killed virus vaccines and in America with living virus inoculated by non-infective routes. Vaccination in all the experiments recorded resulted in a striking increase of serum antibodies. In America the reduction of the incidence of febrile respiratory disease in vaccinated groups as compared with control groups during subsequent epidemics augured well for the possibility of controlling epidemic influenza in the future. In England an epidemic broke out too soon after vaccination for the results to be of much value. The problem of efficient prophylaxis was complicated by the fact that antigenically different virus strains existed. The differences could be demonstrated either by cross-neutralization tests with virus strains and their homologous antisera, or by cross-vaccination experiments in mice. Such experiments showed however that different strains possessed some antigenic components in common. It was hoped that an efficient prophylactic might be obtained eventually by the inclusion of several strains.

At a meeting of the Midland Mental Pathological Society held in the Anatomy Department of the University of Birmingham on March 24 Mr W. GREY WALTER (Research Fellow at the Central Pathological Laboratory of the London County Mental Hospitals) gave a lecture on the electropathology of the brain. He described in detail the apparatus employed and discussed the findings with the aid of a considerable number of illustrations. He also gave a practical demonstration on a case in which rhythmic disturbances characteristic of epilepsy were well shown. The lecturer's able exposition made the simplicity of the apparatus and the ease of its application a pleasant surprise to the members and the discussion which followed showed the interest that had been taken and the possible practical usefulness of the apparatus in mental hospitals.

### SCOTLAND

#### Population of Scotland

An address dealing with the maintenance of population was given by Mr J. G. Kyd, Registrar General for Scotland at a meeting of the Edinburgh City Business Club on March 8. He said that the rate of increase had been diminishing steadily during the last seven years although the population of Scotland was not yet decreasing. There was a probability that the number of deaths would go up owing to the gradual ageing of the population notwithstanding that there might be an actual improvement in the mortality age by age. Overseas emigration on a large scale had ceased although the outflow of people southwards across the border had shown an increase during the last eight years. The average early loss by emigration in the first thirty years of the century was much greater than the yearly loss by death among Scottish soldiers in the war and the total loss in these thirty years had been more than ten times as great as the number of Scottish soldiers who died in the war. The birth rate for Scotland was higher than that for England and the fertility of Scottish women was about one-third greater than among English women. The death rate in Scotland was however slightly higher than it was in England but the rate of natural increase—that is the difference between birth rate and death rate—was about 50 per cent higher in Scotland than in England. England however gained by immigration while there was a loss to Scotland from emigration.

#### Scottish Chiropodists

At the recent annual dinner in Glasgow of the Scottish Branches of the Incorporated Society of Chiropodists Mr John Bruce said he was glad to have an opportunity of paying a surgeon's tribute to the contribution that chiropody was making to the health and well-being of the community. This was not an absurd cult orfad of fashion but was an application of skill which brought to one of the most disturbing of human ailments. Recognition of this work had been tardy but chiropodists enjoyed the confidence of those medical men with whom they had come in contact. It was an impressive fact that last year 50,000 people received help from the various institutions controlled by the Incorporated Society of Scottish branches. Edinburgh had provided the greatest number with 20,000 but even these figures represented merely the fringe of the problem which faced chiropodists. In the not far distant future inspection of school children and adolescents entering factories would probably be a routine part of industrial supervision and the prospects of chiropody as a career would be increased.

#### Child Welfare

Speaking at a meeting of the Edinburgh Women Citizens Association Professor Charles McNeil of the chair of child life and health at Edinburgh University said that in the last twenty-five years the death rate in Scotland during the first year of life had fallen from 100 to 82 per 1,000 births but in England the rate was only 69 and in New Zealand 51. To reduce the Scottish figure it would be necessary to improve the machinery for protection of child life chiefly by improving existing social arrangements for maintenance of health. It would be well to entrust the trained health nurse with more responsibility and to give her better training as had been done in New Zealand. The guardian of the young

child was the mother and if she was given the necessary knowledge much could be done to preserve child life. Many years ago an institute had been established in Paris where child ailments were studied and mothers instructed how to deal with them, and this had resulted in a substantial reduction in the death rate of infants. Twenty years ago in Edinburgh a similar idea had been advocated by Sir Leslie Mackenzie and the speaker would like to revive this, because in the new maternity hospital which was being built there was a centre where students and maternity nurses could be trained in the treatment of young children. This could be made a centre of national education for the training of health nurses.

### Ulster Medical Society Annual Dinner

The recent annual dinner of the Ulster Medical Society, which was held in the Whitla Medical Institute, Belfast, was memorable for the presentation to the Society of two magnificent portraits, one of Sir William Whitla painted by Mr F McKelvey, and the other of Sir Hans Sloane, painted by Mr Clifford Hall. These were the generous gift of the president, Professor W W D Thomson, who presided at the dinner. Sir Thomas Houston unveiled the portrait of Sir William Whitla and Sir Humphry Rolleston that of Sir Hans Sloane. It is particularly appropriate that a portrait of Sir William should occupy a place in the Institute which bears his name, and which was his gift to the profession of Ulster during his lifetime. The Society is proud of the possession of these gifts, and they can be assured of a permanent place in its collection. The dinner was also the occasion of the presentation of Honorary Fellowships of the Society to Sir Humphry Rolleston, Sir Robert Johnstone, President of the British Medical Association, and Colonel A B Mitchell. The scrolls of the Fellowship, hand-painted and bound in morocco leather, were handed over by the president, who referred in felicitous terms to the outstanding services each recipient had rendered to medicine. Sir Robert Johnstone's Fellowship was conferred *in absentia* the scroll being given to him at a subsequent meeting of the Society. The toast of the new Honorary Fellows was proposed in very happy terms by Dr Robert Marshall and was responded to by Sir Humphry Rolleston. Professor P T Crymble proposed the toast of the guests and this was responded to by the Right Hon J H Robb and Professor W B Morton.

### The Belfast Hospital for Sick Children

The annual report of this hospital refers to the loss sustained in the death of Dr Malcolm B Smyth, a son of one of its joint founders. Reference is also made to the Clark benefaction whereby the hospital receives the sum of £15,000 for the erection and equipment of a block to be used for paying patients. Plans for this extension are at present being considered and there seems to be no doubt that this will prove a welcome addition to the services this hospital renders to the public of Northern Ireland. The total expenditure for the year amounted to over £8,900 there being a deficit on the year's working of almost £1,000 which had to be met from capital. The hospital continues to extend its usefulness as shown by the figures in the medical report of 61,582 out-patients in the extern department, 1,468 admissions to the intern department and a total of 2,500 operations. The extent to which ancillary services are used is indicated by the fact that 2,447 patients were examined in the x-ray department. The hospital is also an important teaching centre, the number of students attending for practical instruction having been ninety-four.

### Classification of Adventitious Sounds

SIR—I am glad Dr W C D Walmsley (March 26 p 702) has drawn attention to the need for simplification and more uniformity in the nomenclature of pulmonary adventitious sounds. I was taught by the late Professor Wyllie, than whom I have known no better teacher of physical signs, that all these adventitious sounds fall under one of three heads: (1) dry sounds, (2) moist sounds, (3) friction sounds. That dry sounds (rhonchi) were either high or low in pitch depending upon the size of the tube in which they arose; that moist sounds were either fine (crepitations), medium, or coarse, again depending upon their site of origin, and that friction sounds were either fine or coarse.

I still believe this classification to be adequate for all practical purposes and I should have liked to use it in the book on *Clinical Methods* to which Dr Walmsley refers but found that so many teachers were using much more elaborate classifications that some compromise was necessary. Perhaps I should have had more of the courage of my convictions—I am, etc.,

London, W 1 March 28

ROBERT HUTCHISON

### Familial Clubbing of Fingers and Toes

SIR—Readers of Dr D R Seaton's instructive article on the above subject in this week's issue of the *British Medical Journal* would, I am sure, be interested to learn from Dr Seaton himself or any other of your correspondents, what he or they believe to be the exact Mendelian dominant which is inherited in these cases. It surely cannot be the clubbing itself, but rather some functional circulatory defect which for mechanical reasons determines the vascular congestion of the extremities on which the clubbing probably depends. I raised this question on page 606 in my recently published book, *The Infant*, in a passage which I may perhaps be allowed to quote in the hope that it may stimulate one of your readers to put the explanation of the pathogenesis of this anomalous condition therein suggested to the practical and easy test of a few blood volume estimations. The quotation reads as follows:

Whatever may be the cause of this condition [clubbing of the fingers] it must be one which will explain its occurrence in both pulmonary and circulatory disabilities as well as in septic conditions. Most of the explanations which have so far been given do not appear to fulfil these conditions. There is reason to doubt that it is due to the effect of toxins acting on the soft tissues of the finger ends—a view commonly held—or that it is due to the mechanical effects of cardiac insufficiency. Dr Jean Smith has made the ingenious suggestion which is supported by some independent evidence that clubbing, especially in cases of congenital heart disease, is caused by an excessive volume of blood in the body, a condition which may well cause a vascular congestion in terminal parts which are not well supported and when the local circulation is carried on under disadvantageous circumstances.

In cases of familial clubbing it may be that for some reason not at present understood there is an inherited tendency for a plethora of blood to be maintained in the circulation—I am, etc.

London, W 1 March 19

ERIC PRITCHARD

## Use and Abuse of Antiseptics

SIR—Mr A C F Hallford's reference (*Journal* March 26 p 702) to my recommendation of biniodol in spirit as a means of sterilizing the hands in my introductory article to the *Surgery in General Practice* series has aroused in me a sense of guilt not in having made the recommendation but for failing to vindicate it when in the following article (December 18 1937) Professor L P Garrod and Mr G L Keynes condemned it in no uncertain way. I was very tempted to reply at the time but as the articles in question were both in the same series a feeling of propriety possibly combined with that of good will appropriate to the season then at hand withheld me. This series of articles is designed to provide the practitioner with simple practical instruction on the conduct of minor surgical procedures so that abstruse discussions as to the laboratory characteristics of antiseptics are rather out of place. It is a fact that hundreds of thousands of operations some of the most delicate nature from the point of view of infection (arthrotomies bone grafts, etc.) have been performed with very successful results when the skin was sterilized with the solution I recommended.

The word sterilized is placed in inverted commas advisedly for everyone knows that absolute sterilization of the skin is impossible even with the most modern antiseptics. It is a relative question which does not arise when dealing with instruments cutgut etc and practical experience shows that such antiseptics prove to be very satisfactory. The controlled experiments of the laboratory fail by reason of the very control which is so often extolled. The only legitimate interest which surgery can possibly have in antiseptics is in their behaviour when applied to the uncontrolled human tissues and here experience will be the only guide. One example of this—and probably an important one from the practical point of view—is the fact that laboratory experiments almost always ignore any detergent effect which an antiseptic may have. This I conceive to be a more valuable effect than that of killing organisms when the skin is under consideration. Wiping over with a fat solvent such as ether abolishes more organisms than the application of the most efficient antiseptic. But there are other very valuable properties which some substances possess (spirit among them) giving them a kind of physical as opposed to chemical bacteriostatic effect to which again the laboratory worker apparently pays little heed.

In a letter I cannot enter further into these effects but their mention will be sufficient to indicate to those searching for the truth that we cannot yet afford to ignore the results of practical experience in favour of the more theoretical knowledge the laboratory provides. There was a time, not long ago when a standard laboratory coefficient was regarded as a good indication of the efficiency of an antiseptic in surgery the modern laboratory worker knows better and takes many other factors into consideration before he expresses an opinion but even so it is my contention that there are still many more factors which he ignores particularly on the physical side of the problem.

While this is so I prefer to be guided by clinical experience despite the criticism that clinical observations are but pseudo scientific. To my mind science is a far greater thing than the mere conduct of experiments in laboratories—I am etc

NORLAN C LAKE

## Safe Milk and Safe Butter

SIR—Dr Emrys Jones's letter in the *Journal* of March 19 (p 68) is a useful reminder that tubercle bacilli may be found in milk products as well as in raw milk. In appealing to the public however we must keep things in perspective. While it is true that farm butter prepared from milk which is not pasteurized may contain tubercle bacilli the point is not very important from the practical aspect since it would appear that 80 to 90 per cent of the butter consumed in this country is imported and almost of it is made from pasteurized cream. Pulhridge writing in the *Lancet* of June 8 1935 records the results of examinations of cream butter and cheese. Of thirty-one samples of raw cream sixteen contained tubercle bacilli and eleven *Br abortus* whereas thirty-five samples of pasteurized cream were free from both contaminants. He examined thirty-nine samples of butter of which twenty came from factories ten from farmhouses and nine were definitely identified as imported. Neither the tubercle bacillus nor *Br abortus* was found in any of these. Samples of cheese to the number of sixty-three were examined thirteen of these were soft cheese in the fresh state or two days old but rather surprisingly none of them contained tubercle bacilli or *Br abortus*. Among twenty-nine samples of hard cheese seven days old or more only four which were seven days old contained tubercle bacilli and of these three also contained *Br abortus*. He points out that autosterilization occurs during the ripening period and one would therefore expect to find contaminants more frequently in soft cheese.

The following passage therefore from the League of Nations Report on the Milk Problem contained in the *Bulletin of the Health Organization* for June 1937 appears to be justified.

In this connexion we may point out that neither butter nor cheese appears to be of any considerable importance in the causation of tuberculosis or undulant fever. Except on farms butter is almost invariably made from pasteurized cream while in hard cheese both the tubercle bacillus and *Br abortus* are usually dead once considerable time has elapsed since the ripening process is complete. Only in farm-made cheese and in soft cheese are there organisms likely to be found alive. The vast majority of milk borne tuberculosis and undulant fever is undoubtedly due to the consumption of raw milk or cream.

In these circumstances while in areas where much farm butter is consumed there may be a case for urging the public to consume butter prepared from pasteurized cream so far as the whole country is concerned the problem is a small one compared with that of milk used as a beverage in the raw state—I am etc

Cardiff March 2

RALPH M F PICKEN

## Pasteurization of Milk

SIR—Dr Halliday Swineland's reference (March 26 p 704) to the report of the Economic Advisory Council's Committee on Cattle Diseases is so limited as to be misleading at least to those who have no ready access to itself. It is true the report recognizes that pasteurization produces in milk some deficiency in vitamin C and D. It adds however certain qualifying propositions. Thus on page 7 the committee writes that it is possible only in relation with infant feeding that these deficiencies can possess significance. On the other side of the coin on milk alone for the supply of the vitamin C and D and the benefits of a milk ration when added to the diets consumed, say by children in the home.

would seem to be exerted by pasteurized no less than by raw milk. And again (p 57) "innumerable healthy children are to-day reared on a diet containing no unpasteurized milk."

Dealing in particular with infants fed entirely on milk, the committee states that any vitamin deficiency can be easily corrected by the addition of certain fruit juices, and adds that such addition "is almost as necessary in the case of raw milk, with its variable vitamin content, as in that of pasteurized (p 38), while the general conclusion of the committee reads "that any recognizable changes of quality induced in milk by pasteurization rightly conducted are as a whole too small to outweigh the great advantages inherent in the protection from infection which the treatment secures and in the public confidence which it inspires (p 38). No one who reads the report can doubt the committee's conviction of the risks attached to the consumption of raw milk and its endorsement of the protective value of pasteurization."

Dr Sutherland's bacteriological inquiries are not within my personal range, but he will no doubt have noted with interest that a recent elaborate series of comparative and controlled experiments on calves conducted under typical commercial conditions led *inter alia* to the conclusion that 'the work failed to show any significant difference in the nutritive value of raw and pasteurized milk,' while 'the use of pasteurized milk however, had a clear advantage in that it preserved the animals from infection through drinking milk containing living tubercle bacilli' (J Wilkie and others *Journal of Dairy Research* Vol VIII, No 3, October, 1937)—I am, etc.,

London W 1 March 28

C O HAWTHORNE

SIR—I desire to correct any erroneous impression I may inadvertently have conveyed to Dr Halliday Sutherland's or anyone else's mind regarding manurial *B coli* in milk. Before milk is pasteurized it is invariably examined bacteriologically at any rate so far as the company with which I am connected is concerned. It is in this raw milk subsequently pasteurized that manurial *B coli* is so seldom found the bulk of the *B coli* found being of non faecal type. If Dr Sutherland had read the whole of my letter carefully he would have seen that I assert that 'milk that has been pasteurized is entirely free from potential pathogenic germs', naturally this includes *B coli* of all types. How can a process that ensures germ-free milk give anyone a sense of false security in face of the fact that unpasteurized milk cannot be said to be free from pathogenic germs of a deadly type? Surely such an assertion of false security is straining at the gnat and swallowing the camel. In the *Journal of Dairy Research* Vol VIII No 3, 1937 this idea of a false security is entirely negated. The passage was quoted in full by Dr Bernard Myers in his letter published in your issue of March 5 1938, p 537.

These are not mythical ideas they are proven facts the result of intensive research by men of high standing searching keenly after the truth and should convince any one capable of logical deduction that the only safe milk we have at present at our disposal for human consumption must be pasteurized. We hear a lot about the terrible results of the destruction of vitamins by pasteurization mostly exaggerated but what is the ratio of value to human life between a slight deterioration (if any) of the nutrient quality of milk by pasteurization—a deterioration easily replaced—and the presence of death-

dealing germs that cannot be removed from raw milk except by pasteurization? That is the question that advocates of raw milk must answer satisfactorily or they must give up the fight—I am, etc.,

Streatham, March, 1938

JAMES KIRKLAND, M B

SIR,—Dr Halliday Sutherland mentions an outbreak of typhoid in Montreal which was traced to a typhoid carrier working in a pasteurizing plant. In this country we have many more carriers of tuberculosis than of typhoid. Here are two instances which suggest that few, if any precautions are being taken to avoid contamination of our milk supplies by such carriers of tuberculosis.

(1) Some months ago a man suffering from advanced phthisis was admitted to a sanatorium in Fife. When asked his occupation he replied 'I am the dairyman in charge of a T T herd of cows'. Such a carrier could easily infect the cows as well as their milk.

(2) A few weeks ago I operated on a young dairymaid for tuberculous cervical glands. For six weeks before operation she had had a discharging sinus in the neck. Incidentally no notification as to her condition had been sent to the public health authorities.

Veterinary inspection of dairy cows alone is not enough. Until the dairy workers also are periodically inspected and "vetted" can we regard any milk as safe unless effectively pasteurized?—I am etc.

Dundee, March 27

F R BROWN

SIR—Having great respect for Dr H Sutherland's experience and attainments I was surprised to read his letter in the *Journal* of March 26. Surely pasteurization cannot be held to remove the stimulus towards the production of clean milk when so many pasteurizing concerns have found, often through bitter experience the necessity for a clean milk to start with, as the heat-resisting bacteria so often present in unclean milk may not only prevent the finished product from reaching the necessary standard but may also foul the plant in such a way as to interfere seriously with work for some time.

Of course milk can be contaminated after it has been pasteurized as I believe, was the case in the Montreal typhoid epidemic, but surely this possibility, which plant managers should always have in mind would hardly have been a suitable part of the now famous advertisement? It amounts to this necessity for care in handling milk is not removed by pasteurization but I do not think this was expected of it. Also there are more reasons for the attempts to eliminate tuberculosis among cattle other than that of producing T T milk. Once farmers realize the possibility of preventing disease, I do not suppose they will tolerate its ravages, quite apart from its effects on milk.

By all means consider the effects on the fertility vitamins of milk but let us also think of the toll bovine tuberculosis takes of infants and potential mothers. If we have to choose which represents the greater menace towards the maintenance of the population level? In these days when even bad causes can muster united fronts let there be no dissension in the ranks of those striving to prevent this other slaughter of the innocents. In this campaign the B M A should represent not only its 37 000 members but also every worker who has ever given a thought to the subject—I am etc.

London W C 1 March 29

EMANUEL AGES

## Cancer of the Lung

SIR—With reference to the recent annotation (*Journal* of March 26 p 652) on this subject some further information may be of interest. In some respects it is possible to bring the Joachimstal (and presumably Schneeberg) miners lung cancers into line with those observed in metal grinders and in the mice exposed to road dust. In all cases besides silica in some form iron is present in the dust. Some of the inorganic contents of the Joachimstal dust resemble very closely those of the road dust which produce lung cancer in mice (see Table). The presence of some form of iron and silica in these dusts is suggestive and further experimental work is in hand dealing with this aspect of the problem.

Some Inorganic Constituents of Dust

	Road Dust	Metal Grinders Dust	Joachimstal Pictet's Dust	Nickel D (old matter)
$\text{SiO}_2$	40 per cent	—	64 per cent	0.7 per cent
$\text{Fe}_2\text{O}_3$	4.5 per cent	—	6 per cent	50 per cent
$\text{Al}_2\text{O}_3$	12.0 per cent	—	17.7 per cent	—
$\text{MgO}$	2.5 per cent	—	2 per cent	—
$\text{CaO}$	14.0 per cent	—	7.7 per cent	—

I am indebted to the Joachimstal mining authorities for the sample of the dust taken from the vicinity of their mines. The analysis was made by the London Government Analyst Drs C J Amor (Mond Nickel Co) and J C Bridges (of the Home Office) have drawn attention to the frequency of lung and nasal cancer in nickel workers. I am indebted to the former for a sample of the dust and the analysis of the old matter. This also contains iron with some silica in addition to large quantities of nickel cobalt copper and arsenic and some lead and sulphur. Of course nickel workers like everyone else come into contact also with road dust. Animal experiments are being conducted with this nickel dust iron and other metals may play some catalytic part in development of lung cancer. Concerning the histology of the mouse primary lung cancers there is now no very great difference between these and human lung cancers. At one time the former were regarded as non metastatic but in the last year or two I have obtained metastases from lung cancers in seven mice. The squamous celled carcinoma is a main type of human lung cancer and is regarded as primary. There is a possibility that such squamous cancers are really secondary to warts on the skin which have become malignant and then regressed or have been removed by cautery or other means. In my mice dusted with dust from tarred roads 70 per cent showed typical squamous-celled tar cancers of the skin and several of these had metastases of similar cells in the lung. It would be interesting in the case of human lung cancer to know more of the history of warts on the skin—I am, etc.

National Institute for Medical Research N W 3 March 26 J ARGYLL CAMPBELL

## "Gonococcus Antitoxin" for Gonorrhoea

SIR—We ask leave to deal with certain points raised by Dr Anwyl Davies in his letter in your issue of March 26 (p 701) in which he refers to our experiences in the treatment of gonorrhoea with so-called gonococcus antitoxin. He states that he cases described in the article apparently received no other treatment than the

antitoxin. Our report indicates quite clearly that this was not so. In most of our cases local treatment in the form of urethral irrigations was withheld only during the period of administration of antitoxin—that is to say for not more than one to three weeks in the very large majority. We would remind Dr Davies that the practice of withholding local treatment during the initial stages is one which has been used very successfully by some highly competent venereologists. We do not consider it possible that the extraordinary discrepancy between our results and his could be due to this possible difference in procedure. In this same connexion we quote the concluding paragraph of a letter written by Dr Davies in your issue of March 6 1937 (p 325) in reply to a criticism of the fact that in his report mention of irrigation and other adjuvant treatment had been omitted.

The question asked by one of your correspondents as to whether adjuvant treatment was employed can be read answered. Some of the cases quoted had no other treatment others were treated along routine lines. After all one does not rely on antitoxin in treating a case of diphtheria or the exclusion of throat sprays cardiac stimulants and allied nursing.

This estimate of the importance of local treatment in gonorrhoea seems to have undergone a change during the past twelve months. Obviously such lack of detail makes it quite impossible to assess the relative parts played by the two forms of treatment in Dr Davies's original series of cases. There would perhaps be some basis for comparison between our results and those recently obtained in the St Thomas's Hospital Clinic if Dr Davies would give us precise details as to the general and local treatment which he is using in addition to the injection of antitoxin and would also state the age duration of the signs and symptoms of the aetiology in these cases and the proportion of them which were found subsequently to have evidence of latent infection.

Dr Davies writes that a number of his patients who have received daily doses of 1 ccm of the antitoxin have been free from serious reactions. As we have said it was also our experience that some of these reactions could be avoided by radical reduction of dosage. At the same time there was no evidence that our patients benefited and in fact ultimate prostration and sepsis was the rule. It would be interesting to know reasons which prompted Dr Davies to use a dosage so much smaller than that which he recommended.

London W 1 March 29

## Somatic Pain

SIR—I was much impressed by Sir Thomas Lewis's article on somatic pain in the *Journal* of February 12 (p 21) but I share Dr James Mennell's surprise (March 12 p 592) that Mr J H Kellgren should have omitted mention of the age old practice of relieving rheumatic excellent article on referred pain in muscle (February 12 p 225). I have used paracenes in cases of chronic muscle pain—lumbago sciatica tennis elbow and the like—for many years and have found it in suitable cases almost invariably successful in a properly performed.

It is well known that muscle tissue is insensitive to pain unless the touch sends it to some degree of spasm, thus providing the adequate stimulus for painful sensation. In performing paracenes for example no pain is felt after the initial prick (sartorial pain) of the needle as it enters

the skin until it strikes that part of the muscle which is affected by the fibrosis, when a pain of the "web" type is momentarily experienced.

The pathology of these painful areas in muscle would seem to fall into two main types

(1) Where the fibres are bound together by fibrous adhesions and their unequal contractile powers cause tension in the sarcolemma, which sets up the local spasm causing pain. This puts the muscle group as a whole on its guard to prevent this happening with subsequent 'protective' limitation of movement. It is this type of fibrosis which does not benefit by paracentesis but is readily cured by manipulation which snapping down the interfibrillar adhesions permits the muscle to act according to the decrees of the nervous stimulation of its group without interference from stimuli arising from tension in the sarcolemma.

(2) Where a number of fibres are sealed up in one or more areas of lymph organized at the periphery to form an encapsulated sac any increase of tension on the wall of this sac 'hydraulically' causing tension on the sarcolemma spasm and pain. It is the momentarily increased tension in the sac as the needle pierces it during paracentesis which causes the pain referred to above. This is the type which, if the area be found is immediately and dramatically cured by paracentesis which allows the escape and absorption of the enclosed lymph and permits free working of the muscle once more.

I consider the injection of novocain (save for the purpose of completely abolishing the slight pain of the process in hypersensitive patients) to be superfluous in this type of case, which is immediately eased by the mere rupture of the sac wall by the needle. In the treatment of the first class of case, however, it is unquestionably a great forward step in technique, as by blocking the painful stimuli it inhibits the local reflex protecting the fibrotic muscle, and allows the opposing healthy muscles to pull the fibrotic ones through their full range of movement, thus painlessly permitting the patient to break down his own intermuscular adhesions. I am no advocate of heavy massage, as by the 'mallet'. If it succeeds in rupturing the encapsulated areas all is well, but if the walls are too tough and it fails, the dull ache that follows would have been unhesitatingly described by Mr Mantalini as 'most demnable'. This subcutaneous surgery is well within the province of the general practitioner, and suffering humanity demands that more attention should be paid to it. But I would warn the practitioner that it needs some training of the tactile sense and a certain degree of experience, and that while "the Colonel's lady and Susie O'Grady are sisters under the skin" he would be wise to tackle the younger sister first!—I am, etc.,

Ashton in Makerfield March 21

GERALD LATHAM

### Treatment of Hay Fever

SIR—During the last two years we have had a hay fever clinic at the Royal Waterloo Hospital and it might be of interest at the present season to give you some of the results that have been achieved. The treatment is as follows

In the first place all cases are investigated and tested out against pollens of various kinds—trees, grasses, flowers, dust, etc. Where a positive reaction occurs—that is to say an urticarial wheal of at least half an inch—the patient is immunized. Usually 0.1 ccm of the appropriate allergen working up by 0.1 ccm a week to 1 ccm is used. We have been using mostly the pollens made by either Allen and Himbury or Duncan Flockhart. In cases in which this treatment has been tried before and little improvement has followed zinc ionization has been used. This usually consists

of three treatments at weekly intervals. The period of ionization varies from three or five to eight minutes and the amperage used is between 3 and 8 according to what the patient can stand. The nose of course is previously anesthetized by applying a solution of novocain 5 per cent. In a further group of cases of vasomotor rhinitis which do not react to either of the above methods and which have exacerbations during the hay fever seasons we have found ten injections of calcium Sandoz associated with ten injections of the patient's blood given intramuscularly of great value. Many of the cases that have a catarrhal bronchitis associated with the condition have benefited by inhalations of oxygen passed over a solution of essential oils through a Collison apparatus.

For the irritability of the eyes we have found the following solution of great help

R. Cocaine 2 per cent	m j
Liquor adrenalin hydrochlor	m xx
Liquor aq rosae	ad 3 ss

In more obstinate cases we have also used ephedrine and merthiolate jelly applied locally.

It will be seen, therefore that a variety of methods have to be used, and in my experience, even when using proved antigens the specific vaccination with pollens alone is not enough. The majority of our cases have been of many years standing, and have had previous therapy along these lines without the desired result being achieved.

To a questionnaire we have sent out to some eighty-four patients we have received fifty replies. Two patients were completely cured for the season, thirty were greatly improved, twelve remained stationary, and in five the condition had become worse. In the last five cases ionization had been used. Hence from our figures improvement occurred in over 60 per cent of cases, cure in 4 per cent, and failure in 34 per cent. We feel that it is necessary to start treatment early in order to obtain the best results, thus relief and immunity treatment should start within the next two or three weeks.

I am grateful to Dr P. M. Deville for helping with the questionnaire and statistical results—I am, etc.,

London W 1, March 17

GERALD SLOT

### Problems of Vitamin B Deficiency

SIR—Regarding the annotation on problems of vitamin B deficiency in the *Journal* of March 19 (p. 630), in the course of which reference is made to the recently published work of M. W. Poole I should like to point out a slight inaccuracy in the last sentence, which reads "and if the more or less negative results are accepted as final it would appear that no supplements of vitamin B to children's diets are really necessary." The word "children" should, of course, be "infants," for the note on Poole's work refers to the latter only. I recently reviewed the subject of vitamin B<sub>1</sub> in the diet of infants and young children, and published the results of a small-scale investigation conducted among babies and toddlers attending welfare centres (*Medical Officer* 1938, 59, 107). Among the findings one of the most striking was that although symptoms of probable B<sub>1</sub> deficiency were negligible in infants under 9 months old—for example anorexia not attributable to other causes was present in only 0.9 per cent, and constipation in 1.9 per cent of 212 infants—such symptoms were quite common in children over 9 months old after which age the diet consists chiefly of solid food instead of mainly milk. Thus anorexia probably due to a vitamin B<sub>1</sub> deficiency was found in 25.6 per cent of 176 children aged 9 months to 4 years, most of them being between 1 and 3 years. Favourable results were obtained by supple-

menting the diet of these children with foods rich in vitamin B<sub>1</sub>. I am almost convinced that when discussing the desirability of supplementing existing diets with vitamin B at any rate as regards that factor known as aneurin or B<sub>1</sub> we should distinguish between the needs of toddlers or older children and those of milk-fed infants—I am etc

Oxford March 22

F J G LISHMAN

### After-effects of Modern Treatment of Carcinoma

SIR—I consider that Mr Percy Furnivall has done good service in drawing attention to the unoward results of the radium and x-ray treatment of malignant disease (*Journal* February 26 p 480). My experience of irradiation therapy in the group of cancers of the lateral fauces to which Mr Furnivall specifically refers closely corresponds with his own. For three years all my cases of faucial cancer were sent for radiation treatment by recognized experts. The results were distressing. Though in some there was initial notable improvement in the malignant condition all relapsed all suffered severely with pain—some intensely requiring large and frequent doses of morphine—all had necrosis of soft and bony tissue and all died within a year except two. Of these two one patient a very early case died within fifteen months from the date of starting the radiation treatment with extensive necrosis and with a large fistula measuring approximately 2 inches by 3-inch from the neck into the pharynx the other died at the end of a little over two years from the time when first seen with widespread ulceration showing no tendency to heal and with necrosis of about a third of the inner surface of one side of the lower jaw.

In these cases it is usually impossible to determine what is the condition with regard to the malignant disease—the inability to open the mouth the sloughy ulcerated surfaces the necrosis of bone and the induration of the soft tissues rendering a distinction between the disease and the effects of the treatment almost impossible and again making it impossible to estimate the prospects of ultimate cure of the cancer if the patient can be carried through the long drawn out misery of radionecrosis. I know nothing of the results of the treatment of these lesions with the radium bomb. It is to be hoped that they will be vastly better than those which have been achieved in the past by radiation therapy—I am etc

Middlesbrough March 20

WM S DICKIE

### Sulphonamide for Prophylaxis in Midwifery

SIR—In a recent article (*Journal* March 12 p 562) Professor R W Johnstone reviewed the results of a trial of sulphonamide for prophylaxis in midwifery. We have been using B W and Co sulphonamide P 0.5 gramme tablets four times a day for four days and as the unit admits patients in labour some may be under treatment for twenty-four to thirty-six hours before actual confinement.

Our results—taking morbidly as a temperature of 100.4 F on two successive occasions within twenty-four hours in the first twenty-one days of the puerperium—when compared with a corresponding period of last year have been quite promising. The morbidity rate of the control series (574 cases) was 25 per cent and of these (twenty cases) one developed breast abscess and only one had streptococcal septicaemia. In the sulphonamide group (581 cases) the morbidity rate was 17 per cent and of these (ten cases) one had breast abscess and one had signs of acute lobar pneumonia on the third day. Of

the ten three had had haemorrhagic streptococcal pneumonia while none had streptococcal or staphylococcal pneumonia.

	Morbidity Rate	Percentage of Morbidity
Control Series	25	100
Sulphonamide Series	17	68

While it must be admitted that comparison for a period one year before is not of great value since during the time that the infecting organisms were common virulence the results suggest a continuance of the treatment. I wish to express my thanks to Mr T S F FPCSC FCOG for permission to publish them—am etc.

F.R.C.O. Junior Member F.R.C.S.

### Coupons for the Sherman Bigg Fund

SIR—Four months ago you kindly allowed me to appeal to the profession to help in collecting coupons for the *Daily Mirror* and *Daily Star* in behalf of the Sherman Bigg Fund administered by the Postal Medical Foundation of Epsom College. As his memorial on March 1 you may be willing to allow me to report the results.

First, may I give you a brief resume of the work of the Sherman Bigg Fund for 1937. The income from Mr Bigg's bequest was £155 and special donations augment it raised the total to £275. For the last three years working of the Fund may be regarded as remarkably satisfactory. From the thirty-two educational grants were made to girls and boys and eight maintenance grants for widows or orphans.

Next, as to the coupon collection. From my friends whose help had been enlisted before I wrote to you more than 20,000 coupons have been secured value over £10. The great bulk of these have come from the medical superintendents of the Earl Lonsdale County Hospitals whose kindness I desire to acknowledge most thankfully. Amongst my correspondents whom I desire also to thank here are about 1,200 coupons 1,000 of these have been received from one of the hospital doctors and if that is so the total essence of the medical profession to my letter has been of the value of no less than three shillings. Any comment of mine about this would be expressed in language more than I could probably use to print so I would not say more than is desirable perhaps you would be so good as to say it yourself. I am, however, still hoping for you to do it to reach me at the end of the month—I am etc.

HENRY PUGH

By Beckett &amp; Sons W.C.I. March 19

\*\* We could trim or comment as to the value of Dr Robinson's contribution and the paper can be done enough—but it may be better to leave it as it is, saying that the profession has done a good deal more in this matter and we hope there will be more to pay off from—ED. B.M.J.

### Corporal Punishment

SIR—I do not propose to discuss the merits of corporal punishment should or should not be abolished but clear that considerable consideration may be given to the merits of the use of punishment in the treatment of the individual as well as the community. The law is not free and it is not free to pay for it—ED. B.M.J.

followed, both accounts must be balanced. Justice between the assaulter and the assaultee is logically effected by inflicting on the former the same amount of pain, distress, incapacity, and expense as was inflicted on the latter. The account between the individuals being thus balanced, justice between the assaulter and the State must be effected by a suitable penalty.

At the present time there seems to be a general disposition to regard justice as a matter solely between the State whose law is broken and the assaulter who breaks it, and if this restricted conception is adopted corporal punishment as a means of justice is obviously illogical, for the State has suffered neither pain, distress, nor incapacity. The crime being impersonal so far as the State is concerned, it may quite legitimately discard the balancing of the account between itself and the assaulter and concentrate its endeavour on trying to prevent him breaking its laws again. Whether this attitude is desirable or not may be debated, but if it is adopted justice is not the word which should be applied to it. If a person who has been laid up for a month with a broken head and other injuries retains any sense of humour, the news that the State is redressing his affliction by an earnest endeavour to dissuade the person who assaulted him from committing a like crime again must surely make him laugh—I am, etc.,

London W1, March 25

VICTOR BONNEY

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

Sir Patrick Laidlaw, FRS, will give the Rede Lecture in the Regent House on Friday May 20, at 5.30 p.m. His subject is Virus Diseases and Viruses.

E. T. C. Spooner, M.A., M.R.C.S., has been reappointed University Lecturer in Pathology, and R. I. N. Greaves, M.A., M.B., and G. P. McCullagh, M.A., M.D., have been reappointed University Demonstrators in Pathology. G. C. Grindley, M.A., has been appointed University Lecturer in Experimental Psychology.

The Managers of the Frank Edward Elmore Fund have appointed J. C. Sinclair, M.D., Toronto, to a studentship from April 1, 1938.

On February 4 the University accepted the offer of the Rockefeller Foundation to provide £8,000 towards the support of research in the Department of Medicine over the five year period January 1, 1938 to December 31, 1942 the amount available in any one year of the grant not to exceed £1,600. The Faculty Board of Medicine now recommends that this grant be used for the establishment of three posts of Assistant in Research in Medicine with a tenure limited to the period of the grant. The General Board concurring with the Faculty Board recommends that these three posts be established from July 1, 1938 and that appointments to them be made by the Appointments Committee of the Faculty of Medicine with the approval of the General Board each for a period not exceeding five years or for so long as the Rockefeller Foundation continues the grant to the University for this purpose whichever period is the shorter.

### UNIVERSITY OF LONDON

At a meeting of the Senate held on March 23 with the Vice-Chancellor in the chair, R. V. Christie, M.D., M.Sc., McGill, was appointed from April 1 to the University Chair of Medicine tenable at St. Bartholomew's Hospital Medical College.

F. R. Winton, M.D., Camb., has been appointed as from October 1 to the University Chair of Pharmacology tenable at University College. Since 1932 he has been Reader in Physiology in the University of Cambridge.

### UNIVERSITY OF BRISTOL

The University of Bristol has invited Sir William Savage, formerly medical officer of health for the County of Somerset, to receive the honorary degree of M.D. in July.

### UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—Doris B. Brown, D. Heap, E. James, E. J. Wayne  
CH.M.—M. B. Khan  
FINAL M.B., CH.B.—*Part I*: A. N. T. Aikman, T. Akroyd, J. B. Ashmore, C. E. Astley, P. D. Bedford, C. H. Boyd, A. Colbert, J. B. Coltman, E. Cope, Patricia M. Dobinson, Ruth Edmonds, G. Farrer, J. Orton, G. R. Bedford, D. Benson, J. Braham, W. A. Bridgwood, W. L. Carruthers, D. B. Feather, Dorothy Hough, R. A. S. Keighley, E. S. Levy, S. Madden, W. Maude, R. B. Ray, G. F. Reid, Phyllis M. Richards, J. F. Robinson, J. W. Scholey, S. H. Segerman, A. P. B. Wain, A. J. Ward, T. I. Watkins, D. C. Williams, Kathleen Wilson.  
DIPLOMA IN PSYCHOLOGICAL MEDICINE—W. Sharp  
DIPLOMA IN PUBLIC HEALTH—J. W. Hobson, R. S. Illingworth, T. W. Smailes

\* With first class honours † With second class honours  
‡ With distinction

The following medals and prizes have been awarded:

Hardwick Prize: J. K. Drucquer, E. W. Jackson. Hillman Prize in Clinical Medicine: I. R. Gray. McGill Prize and Edward Ward Prize: W. M. H. Shaw. Infirmary Scholarships: D. L. Richardson and R. I. T. Lloyd. Essay Prize in Anatomy and Physiology (Obstetrics and Gynaecology): I. B. Gartside, commended: R. E. Shaw.

### UNIVERSITY OF SHEFFIELD

The following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—*Parts II and III*: G. E. Wright (with second class honours), A. K. Beardshaw, R. B. Davies, H. D. Elliott, W. L. Rose, J. W. Wier.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At the monthly meeting of the Royal Faculty of Physicians and Surgeons of Glasgow with Dr. John Henderson in the chair, Samuel Lazarus, M.D., M.R.C.P., was admitted a Fellow of the Faculty.

## The Services

### EFFICIENCY DECORATION

The King has conferred the Efficiency Decoration of the Territorial Army on Colonel G. J. Linklater, O.B.E., Major C. B. Jones, Major D. R. Jones, Major J. Rigby, and Major D. Ross.

### DEATHS IN THE SERVICES

Colonel THOMAS EDWARD DYSON, Bombay Medical Service (ret.), died at Monte Carlo on March 22, aged 77. He was born on November 26, 1860, the son of the Rev. Simeon Dyson of Idle, Yorkshire, and was educated at Edinburgh where he graduated M.B., Ch.B. in 1883. He entered the Indian Medical Service as surgeon on September 30, 1886, attained the rank of colonel on January 12, 1914, and retired on January 10, 1919. He received the Kaisar-i-Hind medal (first class) on November 9, 1901. He had been a member of the British Medical Association for thirty-four years.

Lieutenant Colonel JAMES DANIEL CROWE, R.A.M.C. (ret.), died at Hove on March 23, aged 93. He was born on November 7, 1844, and was educated in Dublin where he took the L.R.C.P. and S.I. in 1867. He entered the Army as assistant surgeon on October 1, 1867, became surgeon major after twelve years' service, and retired on December 31, 1887, with the honorary rank of brigade surgeon. Subsequently he changed to lieutenant colonel under the notification of August 9, 1898. In the old regimental days he served in the 21st Foot, the Royal Scots Fusiliers, and in the Royal Artillery. There must be few men still living on the retired list of the Royal Army Medical Corps who served as regimental officers. After retirement he was employed at Weymouth. He had been granted the bronze medal of the Royal Humane Society.

## Medical Notes in Parliament

The House of Lords this week discussed foreign affairs and made progress in Bills. The House of Commons spent a day on Scottish business and also considered the Cinematograph Films Bill and the Coal Bill.

The Hairdressers (Registration) Bill was rejected by the House of Lords on second reading on March 2. In the House of Lords on March 29 the Royal Sheffield Infirmary and Hospital Bill was read the third time and passed. Later that day the Bill was read a first time in the House of Commons. The Housing (Financial Provisions) Bill was read the third time in the House of Lords on March 29 and passed.

The committee stage of Viscount Dawson of Penn's Infanticide Bill is set down for Thursday April 7 in the House of Lords.

The Divorce and Nullity of Marriage (Scotland) Bill and the Marriage Bill were each read a second time without debate by the House of Commons on March 22. On March 29 Sir Kingsley Wood presented the Housing (Rural Workers) Amendment Bill which amends the Housing (Rural Workers) Acts 1926 and 1931. On the same day the Housing (Agricultural Population) (Scotland) Bill passed through report stage and was read the third time. The Criminal Procedure (Scotland) Bill was read the second time.

### Morale of Air Force Officers

In the House of Commons on March 21 the Air Estimates were considered on report.

Mr GARRO JONES referred to the morale of officers in the Royal Air Force and the consumption of alcoholic liquor. He said that unless that source of weakness was carefully watched and kept under control it would affect the efficiency and nerve of pilots in the Force.

Mr CHURCHILL said that all he had been able to learn supported the view that there was no ground for any general stigmatization of the habits which prevailed in the Air Force.

Colonel MURHEAD said that the question of officers drinking had been raised with him privately by a number of people. They were very anxious to know whether every check was kept on the physical and with it the mental capacity of pilots and whether every step was taken to ensure that any deterioration in morale or capacity was noted. It was necessary for the medical officers to have constant contact with the pilots not only in their work but in their ordinary life and games so that any deterioration in morale or efficiency would be noticed at an early stage. He was sure members would like to be reassured on that point.

The Vote was agreed to.

### Admission of Austrians to Britain

On March 22 Sir SAMUEL HOARE said that the policy to be adopted as regards the admission of Austrians to this country had received the careful and sympathetic consideration of the Government. He was anxious that admission should not be refused to suitable applicants including persons whose work in the world of science or arts or business and industry might be advantageous to this country. It must be remembered that even in the professions the danger of overcrowding could not be overlooked while in the sphere of business and industry the social and economic difficulties must be taken into account.

Replying to Mr BEVAN Sir SAMUEL HOARE said that whether an individual should practise his profession in this country was a question for the professional organizations.

Mr MANDER asked if any special machinery was going to be set up to help and guide these professional and other people on their chances of coming in. Sir SAMUEL HOARE

said it would be necessary to have some further organization. He was informed that discussions would be needed between the Foreign Office and other authorities and perceiving those discussions he could not add to the announcement he had made.

### Treatment of Rheumatism

Sir KINGSLEY WOOD was asked on March 24 whether he would set up a committee to consider the best methods of the treatment of rheumatism and the provision of facilities for the treatment. He replied that work in this connection was already undertaken by the Empire Rheumatism Council in co-operation with a special committee of the Royal College of Physicians. The Medical Research Council also carried out and assisted research in the various aspects of this disease.

### Food and Drugs Bill

The second reading of the Food and Drugs Bill was moved in the House of Lords on March 24 by Lord GAGE. He said this was the third Bill dealing with local government and public health based on the work of a Departmental Committee appointed in 1929 originally under the chairmanship of Lord Chelmsford and subsequently under Lord Addison. The Bill dealt in the main with the law of food and drugs but included provisions relating to markets, slaughter houses and cold air stores. The Bill did not deal with matters of weight and measures. As the law relating to adulteration of food was the same in London as elsewhere the present Bill covered the County of London. It consisted of 102 clauses and four schedules. Part I contained general provisions as to food and drugs and re-enacted the major part of the Adulteration of Food Act of 1928 together with provisions from the Public Health Act 1875 dealing with the seizure and condemnation of unsound food. It also included power for the Minister of Health to make regulations on the importation, preparation, storage, sale and delivery of food. Part II dealt with milk, dairies and artificial cream and in the main reproduced provisions from the Milk Acts of 1915 and 1922 and the Artificial Cream Act of 1927. Part III dealt with certain other kinds of food the most important being bread and flour. There were also Part IV on importation offences, Part V on markets and slaughter houses and Part VI on enforcement of legal proceeding. The Bill combined consideration with a limited amount of amendment. The Government proposed to invite the two Houses to appoint a Joint Select Committee on it.

Lord MARCROFT said the Bill should provide that when bread or any food was delivered at the consumer's house it should be protected against insanitary handling. He also referred in the Bill about delivery of milk. Although trouble was taken to produce pasteurized milk and clean milk yet the milk had to be poured out of a bottle that had been left in a cold house and there defiled. The public was trusting to pasteurization but was swallowing filth. The Bill should empower local authorities to prevent the exposure of foodstuffs for sale at ground level where they might be defiled by dogs.

Lord ADDINGTON, as chairman of the Departmental Committee which drafted the Bill, said they had been unable to include all the regulations regarding cleanliness of food when they would have liked to bring in. But the Minister might make Milk and Dairy Regulations dealing with the distribution of milk, the scalding or closing of churns and other vessels and the abstraction of fats. They had gone as far as they could consistently with the present law in this direction. Another clause allowed regulations to be made for preventing danger to health in the exposure for sale and delivery of bread or flour. The regulations would largely cover the points Lord Marcroft had raised.

Lord STRAPOLSKI asked for prohibition of the practice of refilling dirty milk bottles by milk round men.

The Bill was read a second time without a division and on the motion of Lord GAGE the House agreed to refer it to a Joint Committee of both Houses.

On March 28 the House of Commons agreed to participate in the Joint Select Committee on the Bill.

**Air Raid Precautions for Hospitals**—Mr GEOFFREY LLOYD announced on March 17 that a handbook would be available shortly on such structural precautions as were possible for the protection of hospital patients staff and buildings against injury in air raids. A survey of the position of the hospitals in London was being made by the Ministry of Health and the medical authorities. Pending the issue of the handbook the Home Office would be glad to advise any hospital. Mr W. T. KELLY asked that the survey should include mental hospitals.

**Medical Relief for Spain**—Miss RATHBONE on March 21 asked the Prime Minister whether in view of the casualties caused by the bombardment of the civilian population of Barcelona and the resultant shortage of medical and nursing personnel medical supplies and anaesthetics the Government would make a grant for these purposes. Mr CHAMBERLAIN said the Government had already made a contribution to the International Red Cross Society for the provision of medical and other forms of relief in Spain and were considering the desirability of a further contribution.

## EPIDEMIOLOGICAL NOTES

### Diphtheria and Scarlet Fever

Diphtheria appears to be on the increase in England and Wales. During the week under review 1,556 cases were notified with 41 deaths as against 1,492 cases in the previous week and 40 deaths. London did not share in this increase, there being 159 cases compared with 170 in the previous week, while 5 deaths were reported in both weeks. Slight increases in notifications were noticed in Eire and Northern Ireland, while in Scotland notifications decreased from 267 to 261.

Scarlet fever continues to decrease in England and Wales—2,307 compared with 2,515—but the number of deaths showed an increase of 2 over the previous week. Notifications decreased in London from 196 to 189, but there were 3 deaths, compared with none in the previous week. Fewer notifications were reported from Scotland, Eire and Northern Ireland, but the deaths were the same as in the previous week—1 each for Scotland and Eire and none for Northern Ireland. The notifications of diphtheria and scarlet fever in England and Wales as a whole remain greatly in excess of the median value for the corresponding weeks of the last nine years while in London diphtheria figures are slightly less and the scarlet fever figures considerably less.

### Measles

In the 125 Great Towns there were 66 deaths from measles compared with 55 in the previous week, of these, 18 (13) occurred in London, 3 (7) in Liverpool, 6 (3) in Manchester, 6 (2) in Plymouth, 2 (4) in Sheffield. The figures in parentheses denote the number of cases in the previous week. The London epidemic appears to have reached its peak, the number of cases reported from the LCC elementary schools having dropped from 2,521 in the previous week to 2,456 in the week under review, while the average daily admissions to the LCC fever hospitals were 94. The number of cases of measles under treatment in the LCC fever hospitals on Friday, March 18 was 2,079 compared with 1,892 in the previous week. On the same day there were under treatment in these hospitals 1,211 (1,275) cases of diphtheria, 830 (840) of scarlet fever, and 271 (271) of whooping cough. The figures in parentheses refer to the numbers in the previous week. Notifications in the eleven metropolitan boroughs in which measles is notifiable for the week ended March 19 were 1,317 (1,214) distributed in the different boroughs thus: Battersea 142 (143), Bermondsey 60 (54), Finsbury 30 (27), Fulham 81 (51), Greenwich 111 (68), Hampstead 68 (69), Lambeth 377 (355), St. Pancras 143 (172), Shore-ditch 31 (17), Southwark 204 (207), Stepney 70 (51). The figures in parentheses denote the numbers for the previous

week. It may be inferred from these figures that the decrease among the older children in the schools is more than offset by an increase in incidence among children under school age although no information is available from the boroughs in which measles is not notifiable. There were 18 deaths—an increase of 5 over the previous week. In Scotland 1,547 cases were notified, compared with 1,718 in the previous week, the figures for Glasgow were 1,037 (1,188), Edinburgh 90 (105), Paisley 55 (79), Dundee 115 (140), Aberdeen 107 (51). The figures in parentheses refer to the notifications in the previous week. During the week there were 24 deaths from measles of which 19 occurred in Glasgow, compared with 16 and 11 respectively in the previous week. In Northern Ireland there were 106 cases, of which 98 occurred in Belfast compared with 171 and 168 respectively in the previous week, while the deaths were 8, of which 6 were in Belfast compared with 18, all occurring in Belfast in the previous week. During the week under review no deaths from measles were reported from Dublin.

### Psittacosis

According to reports in the Press an outbreak of sickness in the Parrot House of the London Zoo is suspected to have been one of psittacosis. A commissionaire who had been in contact with the birds has died in hospital "of a fever resembling psittacosis." Three keepers from the Parrot House are also reported to be ill. A leading article on the control of psittacosis appears in this issue at page 737.

### Cerebrospinal Fever

In the *Weekly Epidemiological Record* of the Health Section of the Secretariat of the League of Nations of March 24 a map of the world is included showing the distribution of cerebrospinal fever in the different countries for the years 1935-6-7. No figures were available from India, South America, and U.S.S.R. The figures show that the seasonal increase in the incidence of cerebrospinal fever, greater than in 1936, was reported in England and Wales, Germany, Greece, France, Italy, Poland, Scotland and Yugoslavia, while there was a decrease in Japan and Korea. In Africa the disease, advancing from the east and south, was encountered in epidemic form in French Equatorial Africa in 1936, and in the northern provinces of Nigeria in the beginning of 1937. It appears to have reached the Niger Territory towards the end of 1937 when during the week ending February 28, there were 273 cases with 178 deaths, bringing the total during the epidemic to 1,084 cases and 572 deaths. In the United States of America 377 cases were reported for the four week period ended January 29, compared with 542 in the corresponding period of 1937 and 670 in 1936.

### Small-pox

The P and O liner *Strathaird* was put in quarantine on its arrival at Adelaide on March 26 because of the death from small-pox of a woman passenger, aged 35 who had joined the ship at Bombay. On March 25 the ship surgeons spent five hours vaccinating unvaccinated passengers and members of the crew.

In the week ended March 19 there were 236 cases of small-pox reported in Hong Kong with 192 deaths, compared with 214 cases and 128 deaths reported in the previous week. During the same week in British India there were reported in Bombay 212 (234) cases of small-pox, in Calcutta 261 (185) in Madras 69 (64). The figures in parentheses refer to cases reported in the previous week.

### Typhus

In the week ended March 12 there were 411 cases of typhus in Morocco of which 70 were at Casablanca, 56 at Marrakesh, 47 at Rabat, 19 at Agadir. In the same week in Tunisia incidence of typhus fell from 100 to 41, in Egypt there were 68 cases, compared with 36 in the previous week.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 19 1938

Figures of Principal Notifiable Diseases for the week and the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 125 great towns (b) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 15 principal towns in Eire (e) The 10 principal towns (b) in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

## Obituary

### R COZENS BAILEY, MS, FRCS

Consulting Surgeon to St Bartholomew's Hospital

Many St Bartholomew's men in various parts of the world will learn with regret of the death of Mr Robert Cozens Bailey, who before his comparatively early retirement from hospital and private practice was well known as an operating surgeon and teacher of surgery. He died at East Cowes, Isle of Wight on March 18, aged 70.

At St Bartholomew's Hospital Mr Bailey had a brilliant student career. In 1890, the year in which he qualified with the English Conjoint diplomas, he won the Bickenbury surgical scholarship and graduated MB and BS Lond with honours in medicine. In 1891 he obtained the MS degree, with gold medal, and in 1893 he became FRCS. Three years later he won the Jacksonian Prize of the Royal College of Surgeons of England for his essay on the pathology, diagnosis, and treatment of diseases of the prostate gland. At the close of 1903, after years of successful teaching in the Medical School, he was elected assistant surgeon to St Bartholomew's and was promoted full surgeon in January 1913.

In the company of his house surgeons and dressers Bailey was always direct and to the point and excelled at bringing out the practical aspects of the matter under discussion. Something definite and clear always stuck in the minds of those who attended his lectures or whom he taught in the wards or the operative surgery room. He was kindly and sympathetic to the individual needs of the student, and his former work in the dissecting rooms gave an anatomical background to his surgical teaching which proved most helpful to pupils after they had gone into practice. With his composed manner, sprucely dressed square figure, abundant locks and moustache, and unfading smile Bailey was a familiar personality in the hospital square and his resignation from the senior staff long before reaching the age limit deprived Bart's of a very able surgeon.

Dr JAMES LOUIS EDGEWORTH SOMERS who has been described as the pioneer doctor of the Mornington Peninsula, Australia, died at his home in Mornington early in February at the age of 74. Born in Roscrea, Ireland, he was educated at Stonyhurst College, England, Dublin and Cambridge Universities and St Mary's Hospital. In 1883 he obtained the diplomas LRCSI and LAH Dublin when he was only 19. While a student in Dublin he was called upon to identify the body of Lord Frederick Cavendish who was murdered in Phoenix Park. In his early years he travelled extensively and practised in South America and Spain. While serving as a surgeon at Fort Juby in West Africa he was seriously wounded in a skirmish and was rescued by a friendly tribe of Arabs with whom he lived for two or three years before returning to civilization. Always very active he regularly rode his horse round Mornington until the day before his death. In the early nineties he went out to Australia and toured Queensland on foot. He then settled in Mornington and built up a large practice extending over outlying districts. Dr Somers held the commission of surgeon captain on the Army Medical Staff of Victoria retiring eventually with the rank of major. At the time of his death he was health officer of the Mornington Council. He had been a member of the British Medical Association for thirty years. He was an intimate friend of the late Sir Roger Casement whom he had known in Africa. On the day before he died he rode on horseback to the local police court, where he presided

over the cases list, after the closing of the court he completed his round of professional visits. Until about two years ago he never missed in winter or summer a daily swim at the Mornington Baths, he was always an enthusiast for open-air recreation, and had been president of the Mornington Racing Club. He was actively associated with the erection of a fine war memorial in Mornington.

Dr ARTHUR DONALD ROBERTS, who died on February 7 at his home in Hampstead, had been a member of the British Medical Association for many years. He studied medicine in Edinburgh and qualified LRCP Ed, LRCS Ed, LRFPS Glas in 1906. He had a long and varied experience. He practised for some time as ship's doctor, and also worked in the Tropics. Later he was engaged in North Wales and South Wales. In 1924 he began practice in Dalston Lane, Hackney, and remained there until last year, when his health gave way. Dr Roberts (writes a correspondent) was one of the kindest of men, and in his daily living was always ready to help all with whom he was in contact. He showed consideration for everybody except himself, and bore his sufferings with fortitude and cheerfulness. To all who knew him—relatives, friends and patients—there remains the memory of a life of good will and of the true spirit of service.

Dr HENRY ERNEST KING FRETTS (formerly Fretz), assistant surgeon to the Weymouth and District Hospital, died at Parkstone, Dorset, on March 14 while on a journey to France. He had been in poor health for the last year or two. Born in the West Indies, he received his medical education in Edinburgh, where he took the triple Scottish qualification in 1910 and proceeded FRCS Ed in 1914. His first hospital appointments were those of senior house-surgeon to the Norfolk and Norwich Hospital and resident surgical officer to the Sunderland Infirmary. During the war he held a commission as surgeon in the Navy, and subsequently returned to the West Indies and practised at Trinidad for about six years. In 1925 he started practice in Weymouth, where he became widely popular. He joined the British Medical Association in 1923, and contributed articles to the *British Medical Journal* in the two following years. He held the certificate of the London School of Tropical Medicine and the second of these articles was on "Transient Glycosuria in Scorpion Stings".

Dr FREDERIC ARCHIBALD HOPE MICHOD died suddenly at Brisbane, Australia, on March 19, aged 65. He received his medical education at St Mary's Hospital, obtaining the diplomas MRCS, LRCP in 1897, and graduating MB Lond in 1898. He went out to Australia and practised in Brisbane, where he was surgeon gynaecologist to out-patients at the General Hospital and physician to the ante-natal clinic at the Lady Bowen Hospital. He received the diploma MCOG in 1929. Dr Michod contributed articles on obstetrical and gynaecological subjects to the *Australian Medical Journal* in 1923 and 1929. He became a member of the British Medical Association in 1910 and was president of the Queensland Branch in the year 1931-2.

A veteran member of the medical profession Dr JOHN FOOT CHURCHILL JP, died on March 24 at West Malvern, aged 95. He was a student of Charing Cross Hospital and qualified MRCS, LRCP, and LSA in 1864. Most of his professional life was spent at Chesham in Buckinghamshire where he held many public appointments and was honorary medical officer to the local hospital. He had long retired from active work, and gave up membership of the British Medical Association at the age of 80.

Dr SANFORD M WITHERS, director of the Denver Cancer Clinic, Colorado, USA, died on March 8 from aplastic anaemia following exposure to x-rays. He was in his forty-seventh year.

McM" writes I am rather interested in Dr. Lore G. Smith's query in the *Journal* of March 12 in 1961. In my area owing to there having been lead in the water some thirty years ago there is a marked renal failure. A cause of death in a large number of the older people. I have noticed as a corollary symptom that they have a dislike of sweet foods and in some instances a corollary sweet taste in the mouth though in 10 or 15 years experience as a physician in Dr. Smith's case I would suggest that Dr. Smith investigates the renal function of her patient when he might find early signs of a uremia. etc

## LETTERS, NOTES, ETC.

**Haematocolpos**

Dr R. L. SONI (Burma) writes: The cases described by Dr A. L. Craddock in the *Journal* of December 25 1937 (p. 1304) are evidently of partial haematocolpos with haematometra. Haematometra in such cases is secondary and follows the non recognition of the haematocolpos. The condition seems to be rare in general practice. I encountered only one case during the last nine years and that was recorded in the *Indian Medical Gazette* (1937, 72, 93). This was in a Burmese girl aged 15, in whom the presenting symptoms simulated dysentery. There was history of amenorrhoea and of two attacks of abdominal colic each lasting three days three and eight weeks earlier. The labia minora in their lower halves were found fused together to form a bulging pouch which contained foul smelling phosphatic deposits, probably derived from the ammoniacal decomposition of urine. The Mullerian duct for an inch or more in its lower part had failed to canalize. A regular dissection had to be carried out to arrive at the blind lower end of the vagina. The final result was good.

**Treatment of Erysipelas**

R. E. N. writes: In his article on this subject (*Journal*, February 12 p. 346) Mr. John Hosford states that sulphanilamide has a profound sometimes dramatic effect: the temperature drops to normal in forty-eight hours or less. There is a much more dramatic treatment which is safer and cheaper. In some twelve cases of erysipelas I have found that an injection of 10 ccm of boiled milk intramuscularly promotes a cure within twelve hours. In one case only I gave a second injection because the temperature had not entirely settled. It would seem that this treatment is too simple to be generally adopted.

**Correct Footwear**

Dr FREDERIC SANDERS (Chingford) writes: Mr. S. T. Irwin (*Journal*, March 19 p. 649) is in error in stating that hallux valgus would not exist if the great toe were allowed freedom until the age of 10. In all children's shoes such freedom exists to-day but the moment the child reaches adult size the shoe trade has nothing to offer except shoes costing thirty to forty shillings usually stamped with some bone-setter's name! One of these days a Minister of Defence will call for statistics of recruits turned down for feet. He will then say to the Minister of Health: 'In future in addition to giving raw milk you will provide for boys shoes of a proper shape and continue to provide them in increasing sizes for any old boy who needs them at half the market value.' This will raise a howl of abuse from the manufacturers who will then be told: 'Very well you provide shoes for the public at a reasonable price made on our lasts and we go out of business. Until you do we stay in it.' The whole problem of men's shoes would be settled in a fortnight. Women's shoes may safely be left to the lady doctors and to Mr. Bernard Roth whose pious horror of a first class actress in sensible brogues doubtless finds in echo in many an orthopaedic heart!

**Supply of Trypsinamide**

Messrs MAY AND BAKER LIMITED (Dagenham, London) write: The references in the technical and lay press to the report of the Medical Research Council have been dealt with in a general way by a statement from the Association of British Chemical Manufacturers. We therefore wish to limit ourselves to the misunderstanding which has arisen owing to the ambiguous wording of the Medical Research Council's report in regard to the origin of trypsinamide. It is true that trypsinamide was discovered in America in the laboratories of the Rockefeller Foundation but it is entirely incorrect to suggest that the trypsinamide used in the Empire since 1925 has been of American origin. Since that date we have supplied all the trypsinamide used here and in the Empire and this has been completely manufactured in our factory. We are able to continue to supply all the trypsinamide required for use here and in the Empire.

**Medical Aid for Barcelona**

Dr H. B. MORRIS, Chairman, Spanish Medical Aid Committee, 24 New Oxford Street, W.C.1, writes: The official casualty list published in Barcelona gives 1,300 dead and 2,000 wounded as a result of the terrible and continuous

air raids last week. In addition over 10,000 people are homeless. We have decided at an emergency meeting to send help to the medical services in Barcelona. Apart from military casualties which have inevitably been severe in the recent Aragon offensive the Spanish Government is now called on to care for thousands of civilians wounded during intensive air raids on Barcelona and other cities. Bombs have been dropped on the most densely populated quarters and the population fleeing into the hills are systematically attacked from the air by machine gun fire. We have ordered ambulances, surgical instruments and medical supplies which will be sent out at once. This is of course, in addition to the already heavy commitments of our established hospitals. Send us anything you can, however small but send it at once.

**Demonstrations of Physical Therapy Equipment**

With the object of stimulating interest in physical medicine a special series of demonstrations of physical therapy equipment were given last week at the showrooms of Stanley Cox Limited at 11 Gerrard Street, W.1. Although the demonstrations were given under commercial auspices no sales talk was introduced and an effort was made with a physiologist in attendance to interest medical visitors in the physical factors underlying this branch of treatment. The principal attention was directed to an apparatus named the 'Indolor', a painless stimulator for muscles and nerves deriving its power from the alternating current mains, and designed to replace the Bristow coil. The cathode ray oscillogram of the 'Indolor' revealed a beautiful wave-form with no after waves of the stimulus so that the natural stimulating impulse of the nerve and that only is artificially reproduced. This was shown in contrast to the cathode ray oscillogram of the Bristow coil which is made up of a damped train of sine waves each of which must cause a corresponding nerve impulse to be set up and the impulses of each group other than the first can produce no further contraction of the muscle but may be a cause of pain to the patient and account for the inconvenience often experienced in treatment by the Bristow coil. Ultra-short wave diathermy was also demonstrated and the characteristics of the energy generated by various systems were well shown.

**Vicissitudes of a Leper**

On February 28 death ended the astonishing career of John Ruskin Earle, a North Carolina mountaineer who contracting leprosy some thirty years ago spent the remainder of his life alternately being confined as a leper, escaping, or being released as apparently cured. The diagnosis was confirmed by Hansen, discoverer of the leprosy bacillus, and in 1917 a special 'leprosarium' was built for him at Carville, Louisiana.

**Dominion Dairy Products**

During the present century science and the organization of modern transport have combined to bring to this country plentiful supplies of dairy products: meat, fruit, and other foodstuffs from all parts of the world. Nowhere has greater progress been made than in the provision of an expensive yet high quality dairy products by the overseas Dominions which are to-day according to the Imperial Economic Committee responsible for half our supplies of butter and three quarters of our requirements of cheese. Concurrently with the post-war increase in Dominion butter supplies Britain's butter consumption has risen by more than 50 per cent, the average during 1937 being 24.7 lb a head (or nearly half a pound weekly). The high and uniform vitamin potency of Dominion butter has been a subject of frequent comment. Typical of such observations is the statement made by the Ministry of Health's Advisory Committee on Nutrition in its report *The Criticism and Improvement of Diets* (p. 5). There is the possibility that butter may be devoid of vitamin D in winter and consequently if butter is being relied upon as a protective food it would be best to specify butter such as New Zealand which is fairly constant in its vitamin D content.

**Correction**

In the sketch of Alexander Skene published on February 12 (p. 349) Long Island Cottage Hospital should read Long Island College Hospital. This institution recently celebrated the fiftieth anniversary of the founding of its Hospital Laboratory when Dr Oswald T. Avery of the Rockefeller Institute for Medical Research spoke on 'The State of Bacteriology Fifty Years Ago and To-day'.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

### 267 Chronic Hepatitis in Young Persons

E. POLACK (*Acta med. scand.* 1938 93 6 614) during the past twelve years has systematically employed the following tests in cases of jaundice treated in a hospital in Copenhagen: Ehrlich's benzaldehyde test for the demonstration of urobilinogen in the urine; Hays's sulphur test for the demonstration of bile acids in the urine; Meulengracht's icterus index determination in serum; Bauer's galactose tolerance test; and Ronas's test for quinone resistant lipases in the blood. The eight patients between the ages of 24 and 29 included two doctors, three medical students and one nurse. In every case an attack of acute hepatitis with jaundice was followed by a more or less chronic hepatitis. All these patients were kept under observation for three to eight years during which time they continued to work although they suffered from lassitude, malaise, a sense of fullness in the right side of the abdomen, and tenderness under the right costal arch. They were subject to exacerbations of their hepatitis for which in some cases no cause was demonstrable but as a rule it could be traced to some slight infection such as a coryza or sore throat. The author points out that an apparently mild attack of acute hepatitis with jaundice may if inadequately treated from the outset develop into a chronic condition with exacerbations of the hepatitis on slight provocation from time to time. He believes that the condition he describes is the primary stage of cirrhosis of the liver. Although he is an advocate of strict and prolonged dietary treatment with plenty of carbohydrates and strict rationing of proteins in the early acute stage of hepatitis he admits that it is not always possible to avert the onset of chronic hepatitis.

### 268 Angina Pectoris and Coronary Disease

I. HOLMGREN (*Hygien. Stockh.* December 15 1937 p 865) reviews his experiences of angina pectoris and allied diseases at the Serafimer Hospital in Stockholm from his appointment as professor in 1913 until 1926. Dividing this time into three eight year periods he notes that in the first period there were only two patients with angina pectoris, in the second thirty-three and in the third seventy. This remarkable rise cannot be dismissed as due solely to improved methods of diagnosis as angina pectoris was as easily and surely diagnosed at the beginning as at the end of the period under review. In the same period thrombosis, infarction or embolism of the heart was diagnosed only once in the first eight years whereas in the second eight years five such cases were diagnosed and in the last eight years as many as thirty-four cases. In this group however, the increased frequency may reflect to a certain extent improvement in diagnosis. This reasoning is confirmed by the observation that all the first twelve cases proved fatal while the mortality was only 26 per cent among the twenty-seven patients treated in the five year period 1932-6. No great advance having been made in treatment the striking improvement in the recovery rate must be traced to the recognition of these conditions at a comparatively early stage. Professor Holmgren calculates that when thrombosis of the coronary vessels is not immediately fatal the patient has a good chance of recovery after a protracted convalescence of three months or more. Approximately half of his cases were within the age group of 56 to 65 years. He is convinced that the striking numerical preponderance of male over female cases of thrombosis, infarction or embolism of the heart is in large part to be explained in terms of alcohol and nicotine.

## Surgery

### 269 Javle's Incision for Appendicectomy

A. CHARBONNIER (*Presse med.* December 25 1937 p 1871) describes the advantages of using a suprapubic transverse incision for appendicectomy or for removal of the right adnexa in young women. This incision leaves a more visible scar and allows of easy access both to the appendix and to the right adnexa, and sometimes the left. The technique described is considered to be superior to that of McBurney in females in whom the caecum is usually in a low position. Other advantages are that the incision can easily be extended in either direction if necessary, allows of satisfactory drainage and avoids the risk of post-operative hernia. The incision is made on the right side transversely from the middle line a finger breadth above the pubis and is about 5 to 8 cm in length. It has been tried out in thirty cases of appendicectomy in young women and has been found to give good exposure and a good cosmetic result in all the cases when the carefully selected. Those which were most suitable were thin or only slightly developed women with the caecum either low or mobile and with suspected lesions of the right pelvic organs. Operation was carried out for chronic or subacute appendicitis in twenty instances and for acute cases associated with gynaecological lesions were treated.

### 270 Atrophy of Articular Cartilage during Immobilization

H. ROUVIERE (*Ann. anat. path. med.-chir.* November 1937 p 721) points out that normal movement of a joint is necessary for the nutrition of the articular cartilage and if the joint is immobilized for a long time rapid changes arise which may lead to ankylosis. There are no blood vessels in the cartilage which receives its nourishment through the synovial membrane. During the day the tonicity of the muscles exerts pressure on the articular surfaces bringing them into contact. This has the effect of excluding the synovial membrane from the joint space. Experiments to prove this have been carried out on the knee joint of a dog which had been decalcified for 48 hours. After the joint had been exposed and the articular cartilage removed it was fixed by a wire round the neck of the femur and the tibiofemoral joint. The model was then immersed for six hours in a solution of methylene blue (1 in 500). It was found that the articular cartilage had no blood vessels. This experiment was repeated with loosely tied rubber tubing to resemble more nearly the pressure exerted by the muscles and the result was the same. This showed that it is not only necessary for the articular cartilage of a joint to be in contact with the synovial fluid but also that it is necessary for the nutrition to be cut off. It is suggested that the complete relaxation which comes with deep sleep is necessary to ensure the nutrition of the articular cartilage. Movement of the joint is also necessary and immobilization may lead to atrophy of the articular cartilage.

### 271 Infiltration Treatment of Joint Injuries

P. WERTHEIMER (*Rev. chir. Paris* November 1937 p 654) points out that the after-effects of a sprain or dislocation or fracture are not always confined to the immediate results of the trauma but may go on to multiple atrophy, contraction or decalcification. It is concluded that trauma produces a short phase of local vasoconstriction which is followed by active vasodilatation. The vaso-motor disturbances may cause a series of pathological changes such as synovial effusion, decalcification of the epiphyses and osteoporosis. A method of infiltration

tion anaesthesia has been tried to prevent these vasomotor changes and to re-establish normal vascular rhythm and function. This treatment is indicated in cases of joint injury when the reflexes which affect the vasomotor equilibrium of the injured limb are involved. It is specially recommended in contusions of the back of the hand or of the instep or shoulder, where oedema, muscular atrophy or osteoporosis may be expected. In cases of sprain affecting the foot, wrist, or knee it has been found that infiltration lessens the pain, limits or reduces the swelling, prevents effusion into the joint, and if effusion should take place facilitates its absorption. Infiltration enables reduction to be carried out easily in cases of dislocation, and may help to prevent permanent injury. This method is not suitable for fractures of the shaft of the long bones or of the ends of the bones, but may be used successfully in certain cases of fracture of the shoulder-blade, of the clavicle, metacarpus, or metatarsus. Infiltration should be carried out as soon as possible, a 1 per cent solution of novocain without adrenaline being used. The fluid is injected into the ligaments and under the periosteum, 10 to 50 ccm being used. The patient is then encouraged to move the injured joint, and this is followed by relative immobilization by means of a sling and rest in bed. Infiltration is carried out until restoration of function has taken place. It has been found to be a safe and satisfactory method of treatment in suitable cases.

## Therapeutics

### 272 Diathermy and Short-wave Therapy

H. G. SCHOLTZ (*Fortschr Ther* January 1938, p. 7) discusses the relative merits of diathermy and short-wave therapy in lesions of the female pelvis. Theoretically short-wave irradiation produces a greater heat in the deeper tissues than does diathermy. In the living subject, however, heat is being continually lost and distributed owing to reflex changes in the circulation. High temperatures in the pelvis can certainly be obtained but are accompanied by general hyperpyrexia. The author found that in investigating the temperatures produced in the pelvis by diathermy and short-wave irradiation large numbers of readings had to be taken in the same patient owing to the fluctuations caused by circulatory changes. No rise of temperature above 1°C was obtained by either of these physical methods. Scholtz is of the opinion that in those areas of the body which are richly supplied with blood short waves give no better results than diathermy provided only that sufficiently large electrodes are used in applying the latter but that they are of more value in those areas surrounded by layers of air—for example the thorax. Short wave irradiation has the advantage over diathermy in that it produces no pain and is very successful in the treatment of acute inflammatory conditions. Scholtz believes that other hitherto unspecified factors play a part in making the short waves therapeutically valuable. In his experience a distance of 2 cm. between the electrodes produced the greatest rise of internal temperature. Larger distances while productive of greater heat in the cadaver did not have the same effect in the living subject.

### 273 Thyroid, Pituitary, and Ovary

J. ADLER MONNICH and R. TIBERTI (*Wien Arch inn Med* 1938, 52, 7-41) allude to recent animal experiments showing that (1) follicular hormone inhibits the increased basal metabolism following the administration of thyroxine and (2) after thyroidectomy the lutinizing effect of prolactin is greatly increased. Choosing the reverse way of testing the hypophyseal thyroid antagonism by its effect on the female genital organs they have found that preparatory

administration of thyroxine in guinea pigs diminishes or abolishes the effect of the gonadotropic anterior pituitary hormone in increasing the size and contractility of the uterus and in the promotion of follicular ripening. In cases of genital hypoplasia in young females or of adiposity combined with ovarian hypofunction it is inferred that the combined therapeutic administration of thyroxine and folliculin and/or prolactin is illogical.

### 274

### Treatment of Rickets

H. U. KOTTGEN (*Med Welt* January 29 1938, p. 162) mentions in connexion with advances in the treatment of rickets (1) the fact that vitamin D<sub>2</sub> (with recent progress in knowledge of the by-products of irradiation of ergosterin) is now available commercially in so pure a form that the therapeutic is 1/3,500th of the toxic dose, and (2) so called shock treatment (*Stoßbehandlung*) by a single dose of concentrated vitamin D<sub>2</sub>. The efficacy of such treatment was discovered by Harnapp, who had found that single doses of an impure product of the irradiation of ergosterin not only cured spasmophilia but also rickets. Eventually he and others found that the dose of pure concentrated vitamin D<sub>2</sub> required for the complete cure of florid rickets is 12 to 15 milligrammes, which corresponds almost exactly with the total amount given in the ordinary therapeutic course comprising daily dosage for two to three months. In the one dose treatment the inorganic phosphates and calcium of the blood serum increase within twenty-four to forty-eight hours, improvements in ossification of the long bones and skull are demonstrable by X-rays within three to five days. This treatment is specially indicated in rickets coexists with spasmophilia and in pneumonia—in which coincident rickets is known to affect the prognosis adversely.

## Dermatology

### 275

### Electrical Reactions of the Skin

S. K. ROSENTHAL (*Ann Derm Syph* Paris, November, 1937, p. 863) describes a new method for measuring the electrical reactions of the skin. He points out that the reaction of the skin is complex, depending upon the state of the horny and deeper layers, and especially upon the permeability of the cell membranes, the tendency of the cells to produce histamine-like substances, the specific sensitivity of the skin, and the blood and nerve supplies. As it would be almost impossible to measure these at one and the same time he has chosen to measure the change in electrical resistance of the epidermis produced by injury. He used 10 per cent caustic potash in view of its well-known action on the epidermal cells, and a reduced continuous current, measured by a voltmeter accurate to a quarter of a volt, and a milliamperemeter reading to one-fortieth of a millimetre. The current passed into the body from the negative electrode—a gauze-covered metal plate dipped in physiological saline—and left it at the point of contact with a platinum electrode applied at the place where a drop of caustic potash had been deposited from the capillary tube. The current was passed for one or two seconds, again a minute later and the milliamperemeter readings were plotted on a graph. One hundred control cases and a number of patients suffering from eczema, psoriasis and asymmetrical skin and nervous diseases were examined and the results show that the skin of patients suffering from eczema is five times more easily influenced by chemical irritants than the normal and that this tendency diminishes when the patient is almost cured. In cases of psoriasis the skin does not show such marked reactivity but the response is least noticeable in those cases which should respond well to treatment. In unilateral conditions such as

hemiplegia the response is less marked on the healthy side. Rosenthal suggests that this method can be used for prognosis in eczema, psoriasis and certain unilateral skin or nervous affections and may be of value in prophylaxis if used as a test in the selection of workmen who have to deal with chemical or other irritants.

## 276 Activity of Sebaceous Glands

A. DESAUX (*Presse med.* November 24 1937 p 1672) discusses the abnormal activity of the sebaceous glands in association with puberty and endocrine dysfunction. A degree of activity of the sebaceous glands which is more than physiological is seen as a result of the action of icteroid intestinal toxemia and avitaminosis with perhaps in addition some disturbance of hormonal balance. Comedones, seborrhoea oleosa and a thick coarse epidermis or even acne conglobata are seen in association with the anterior pituitary changes leading to acromegaly and gigantism. Excessive seborrhoea is also observed in hyperthyroidism and pulmonary tuberculosis and adenitis patients showing especially rapid hair growth and loss of hair pigment brittle nails and hyperidrosis. The association of abnormal activity of the sebaceous glands with menstruation is confusing for it may be seen both in those women who have irregular and scanty menstruation and in those who are regular and normal and even in women showing signs of virilism. Possibly this is due to the prolonged and uninterrupted flow of folliculin into the blood from follicles which have matured but not ruptured acting in the same way as it does in the enlargement of a young girl's breasts. In animals excess of sebaceous secretion is seen following injections of corpus luteum hormone. Finally Desaux concludes that the whole dermal covering should be considered as a vast gland secreting hair, nails, sebum or keratin the activity of which is enhanced by growth by the secretions of the anterior pituitary and the thyroid and by cholesterol like bodies containing the oestrogenic principle similar to those which may produce cancer.

## 277 Bakers Eczema

J. R. PRAKKE and C. POSTMA (*Nederl. Tijdschr. Geneesk.* January 22 1938 p 367) review the literature and discuss the reasons for distinguishing bakers' eczema from eczema in bakers. Patch tests made with a 1 per cent and a 5 per cent solution of ammonium persulphate were strongly positive in fourteen out of fifteen bakers with eczema of the hands and forearms negative in five out of six bakers without eczema (the sixth who gave a positive reaction had had bakers' itch some years previously) and negative in fourteen controls one of whom was a normal individual while thirteen had eczema. The authors maintain that flour improvers containing persulphate play an important part in the production of bakers' eczema.

## 278 Epulis Granulomatosis

S. AYRES and N. P. ANDERSON (*Arch. Derm. Syph.* Chicago December 1937 p 1149) report a case of epulis granulomatosis occurring in a man aged 80 after the extraction of carious gold stopped teeth in the lower jaw. There was a cauliflower-like tumour, which seemed less hard and white than an epithelioma without any associated leucoplakia or adenitis. The condition has to be differentiated from fibroma, sarcoma, teratoma and carcinoma. Biopsy is essential for diagnosis. Excision should be done with a diathermy knife and the surrounding area well desiccated. The carious teeth should be removed, the lacerated surface of the gum painted with 2 per cent methyl violet in water and the affected area irradiated with unfiltered rays or a radium half-strength plaque applied for twenty-five minutes. In this case there was no sign of the disease after four months.

## 279 Virus Diseases in Dermatology

R. T. BRAIN and B. LEWIS (*Brit. J. Derm. Syph.* December 1937 p 551) discuss the difficulty of investigating virus diseases affecting the skin because the viruses produce such a variety of skin lesions with different degrees of inflammation in the cells of the skin. The size of the virus lesion bears little relation to the amount of virus present. Virus infections are associated with inclusion bodies in the cells and the involvement of particular cells—for example the nerve cells in rabies. Inclusion bodies may include the organism and in certain cases the virus itself is visible. It is difficult to differentiate true inclusion bodies from granular degeneration. To confirm the diagnosis it is essential to prove that the infective agent is not bacterial and this has to be done by animal inoculation. Here the difficulty lies in the varying susceptibilities to virus infection of different animals. The virus of herpes can easily be inoculated into the planar pad of a guinea pig's foot and those of dermatitis herpetiformis and pemphigus have also been conveyed to guinea pigs and rabbits. Blood from a suspected case may be centrifuged and tested for agglutination or a neutralization test may be done. The authors describe a case of Kaposi's varicelliform eruption, this disease has features suggesting an acute virus infection. The condition is clinically indistinguishable from generalized vaccinia but is seen in association with infantile eczema or Benier's prurigo. They report the case of a boy aged 15 who was vaccinated at the age of 3 months. Eczema developed one week after this followed by the typical asthma-eczema-prurigo syndrome. Before the onset of the present illness the boy had been anxious about his examinations, he developed a papulo-pustular eruption on the face with cervical adenitis. The lesions were umbilicated and associated with high fever and mainly distributed on the face and neck. Blood culture was negative, culture from skin lesions yielded *Staphylococcus pyodermae* and there was a haemolytic streptococcal infection of the throat. The fluid from blisters was injected into the pad of a guinea pig, pus formed and a specimen of this was transferred to the scarified cornea of a rabbit and from that rabbit to others. The post mortem and other findings were indefinite.

## 280 Hepatic Function in Skin Diseases

V. GENNER and T. K. WITH (*Hospitalstidende* December 7 1937 p 1241) have investigated at the Frøen Institute in Copenhagen relationship of certain skin diseases of hitherto unknown origin to disorders of metabolism traceable to the liver. If they argue functional disturbances of the liver are responsible for certain diseases of the skin, it should be possible to establish a causal relationship between the two by systematically applying certain liver tests to a large number of carefully selected cases of skin disease. Of the 165 patients tested 104 suffered from lupus vulgaris, seventy-four from psoriasis, 102 from eczema, fifty-nine from pruritus and prurigo and twenty-six from Benier's prurigo. The functions of the liver were examined by Bauer's galactose test, Rona's lipase test, estimation of Meugracht's jaundice index, Ehrlich's serial turbidimetric determinations and Folin's test for bile acids in the urine. In nearly all the cases these investigations were conducted on the patients so that the reaction of the diseases of the skin to treatment could be closely followed and correlated with the findings of the liver tests. It was noted that the applications to the skin caused transient interference with the functions of the liver. In other respects the findings were almost entirely negative and gave no support to the theory that hepatic disorders are the cause of most of the skin diseases investigated. The authors conclude that in the case of prurigo and eczema a causal relationship exists external to the body in conjunction with individual

peculiarities of the skin must be held responsible and they suggest that the more or less heroic dietetic limitations imposed on many patients suffering from diseases of the skin lack a sufficiently scientific rationale justifying the hardships inflicted

## Obstetrics and Gynaecology

### 281 Prontosil in Pregnancy

G ALSTEAD (*Ugeskr Laeg* December 16, 1937 p 1347) reports from Professor Meulengracht's hospital in Copenhagen three cases—the last fatal—in which drugs of the prontosil group caused serious poisoning. The first patient was a woman, aged 42, in the seventh month of pregnancy. Signs of infection of the urinary tract led to the administration of 0.6 gramme of prontosil rubrum three times a day. In the afternoon of the first day of this treatment the temperature rose to 104° F. Next day she was very drowsy, and cyanosis was detected but her dysuria and lumbar pain had completely disappeared. The cyanosis having become alarming, and the patient's general condition being disquieting, the prontosil was discontinued after altogether 4.2 grammes had been given. During the next few days the temperature fell and the general condition improved, but the cyanosis did not begin to disappear till the drug had been discontinued for four to five days. A neutrophil leucocytosis, methaemoglobinæmia, and later, severe jaundice were also observed in this case. In a second case, that of a woman aged 54 given 0.6 gramme of the drug three times a day for a tonsillar infection, a severe urticarial rash broke out after she had been given altogether 4.2 grammes. At the same time the fever and sore throat vanished. After describing a third case that of a woman, aged 31, much debilitated by a protracted puerperal infection and given injections of prontosil the author suggests that the risks and advantages of treatment with the prontosil group of drugs should be carefully weighed against each other. Sulphanilamide would seem to be contraindicated during pregnancy and when there is impairment of the renal and hepatic functions.

### 282 Phlegmasia Alba Dolens after Abortion

J SPINDLER (*Bull Soc Obstet Gynec* December, 1937, p 750) reports three cases of phlegmasia alba dolens following abortion. This is considered to be an uncommon condition, no case being reported in the *Bulletin* between the years 1920 and 1936. The question is raised why phlegmasia should so rarely follow abortion, which is often criminal and consequently septic, when it is a comparatively common sequel of full-time labour.

## Pathology

### 283 Comparison of Human and Cow's Milk

R. H. A. PLIMMER and J. LOWNDES (*Biochem J* October 1937 p 1751) have carried out detailed analyses of human milk to determine the distribution of nitrogen as caseinogen as lactalbumin and as non-protein nitrogen, the nitrogen sulphur phosphorus and the various amino-acid contents of the proteins and the calcium and inorganic and total phosphorus contents of the milk. Comparisons were made with cow's milk. Although the compositions of the two proteins from the two types of milk are in general similar there are marked differences in the phosphorus and cystine contents of human and cow caseinogen. Cow's milk contains two to three times as much of most components as does human milk, the same amount of cystine however occurs in both milks.

Dilutions of cow's milk with an equal volume of water therefore reduces the cystine content to half that of human milk. If methionine can replace cystine in the nutrition of the human infant, half-strength cow's milk contains enough sulphur-containing amino acids as compared with human milk but if cystine is not replaceable by methionine then 16 mg of cystine should be added to each 100 ccm of half-strength cow's milk to make up the deficiency. Dilution of cow's milk with twice its volume of water may reduce the tryptophane and arginine contents to below those of human milk.

### 284 Adrenal Deficiency

R. RIGLER (*Wien klin Wschr* December 24 1937 p 1731) alludes to the views that adrenal insufficiency interferes with oxygen consumption with carbohydrate metabolism and with the circulation, respectively. He considers at length the more recent theory which attaches chief importance to the disturbance of water and salt metabolism. The last view is supported by (1) the power of sodium chloride administration to relieve symptoms of experimental adrenal resection and of patients with Addison's disease, (2) the increased potassium ion plasma concentration in adrenal insufficiency, (3) the negative sodium balance in Addison's disease, (4) the occurrence in dogs which have been deprived of sodium ions by the intraperitoneal injection of glucose and subsequent paracentesis, of diminished blood volume and pressure, increased sensitivity to bleeding, and other signs and symptoms all of which are noted after experimental adrenal ectomy. It is known that adrenalectomized rats fail to respond to phloridzin or starvation by ketone body excretion. Rigler has found that the same is true of animals "de-salted" in the manner described and that oral feeding of the abstracted salt (but not of its sodium in combination other than with chlorine) restores the ketonuria. It is concluded that the diminished ketogenesis after adrenalectomy is a secondary consequence of disturbances of mineral metabolism and/or acid-base equilibrium not of renal origin. That the salt loss in adrenal deficiency may in part be due to the disturbance of renal reabsorption of salt is still a possibility to be reckoned with. Rigler found that in "de-salted" animals as in those from whom the adrenals had been removed, the capacity for diuresis in response to large amounts of water was to a very large extent lost.

### 285 Adrenaline Inactivation

W. A. BAIN, W. E. GAUNT and S. F. SUFFOLK (*J Physiol* December 14 1937, p 233) have studied by a method of 'continuous assay' the rate of inactivation of adrenaline in cat's blood, plasma and serum, with and without added tissue extracts or slices. In plasma and serum inactivation proceeds slowly to completion more rapidly in serum than in plasma. The blood inactivation reaches an equilibrium at about half the initial concentration of adrenaline and proceeds no further. Addition of tissue slices or extracts leads to complete inactivation of adrenaline in blood, liver being the most effective. This action of tissues is prevented by boiling them and is diminished by increased acidity or absence of oxygen but not by cocaine or cyanide. The active adrenaline in a blood adrenaline mixture at inactivation equilibrium is entirely in the plasma but there is also adrenaline associated with the corpuscles which can be released by separating the cells and laking them or by plating them in Locke's solution or fresh plasma or serum. By taking an equilibrium mixture 80 per cent of the adrenaline added to blood can be recovered. The fate of the remaining 20 per cent is not known. It is not clear in what form the inactivated adrenaline is held by the blood cells. The relationship of the results to the inactivation of adrenaline *in vivo* is discussed.

# ADEXOLIN RE-CREATES RESISTANCE

A PRODUCT OF THE  
GLAXO LABORATORIES

The aftermath of winter infections is frequently marred especially in the young by complications or relapse. To make certain that convalescence leads to uninterrupted recovery, no better weapon exists than ADEXOLIN. Its vitamins A and D recreate the depleted defences and reserves of the body and rapidly restore the tissues to normal health.

Among children, infection is often followed by an increased susceptibility to the common cold, bronchitis or pneumonia. In such cases ADEXOLIN enhances the constitutional resistance against secondary infection and promotes the rapid normalising of the tissues.

Among adults, after being laid up by infections such as influenza, the patient is often weakened and depressed by the lowering effect of the illness. By accelerating recuperation and building up the general well-being, ADEXOLIN expedites the return of the patient to full health.

## ADEXOLIN Capsules

# MENFORMON TABLETS

to reverse menopausal changes

Finally there is one important observation that I would bring to your notice. Patients treated with oestrin for whatever complaint frequently volunteer the information that they experience a sense of well-being. All of us suffer only too frequently from the voluble and disconcerted menopausal patient with all her aches and pains and I have been gratified by the CHANCE OF MENTAL ATTITUDE which oestrin has afforded to some of the patients converting them almost into cheerful kindly rays of sunshine.

## Prepared for the mouth and throat

'Dettolin' is specially made to kill quickly the micro-organisms concerned in affections of the mouth and throat. It contains, among other ingredients, the active germicidal principle of 'Dettol'—the modern antiseptic. For all its high germicidal efficiency, 'Dettolin' is soothing and gentle on delicate tissue. It has the added advantage of being distinctly pleasant to use, an important factor when frequent and regular gargling is prescribed.

'Dettolin' is obtainable from Chemists and Medical Suppliers  
Price 9d and 1/3 Sample and full information on request

# A FURTHER ANNOUNCEMENT BY MAW THROMBIN-COAGULANT-MAW DRESSINGS

FOR THE MAJOR OPERATION OR THE MINOR CUT

## *The Physiologically Correct First Dressing*

Some time ago, we announced the production of Thrombin-Coagulant-Maw a preparation of remarkable efficiency for clotting blood

We now offer a range of Surgical Dressings known as Thrombin-Coagulant-Maw Dressings, to which this preparation has been applied with such regard for the scientific principles concerned, both chemical and physiological that we venture to suggest a new method of treatment has been found

Whenever a wound is accessible to the application of a Dressing, TCM Dressings will be found of great value in controlling unusual cases of stubborn haemorrhage. They are very reasonable in price and represent a true economy of your own time and money, whenever haemorrhage has to be treated

*Laxatives*, it is well known no drugs have no essential character of their own.

The must be biological i.e. the must coordinate and imitate in their action the natural physiological processes of the intestine. The must be capable of educating the intestine so that the habit of a laxative is not to be needed and the intestine can function unaided when a normal adjustment is attained.

*Taxol* is a biological laxative.

*Taxol* has no effect on the action of the intestine and purgation, but stimulates the intestinal processes which resemble those of nature. The intestinal gland, which is an important part of its composition and of the intestine by reinforcing the digestive function. It has a cumulative action upon the stimulating action, gentle and does not force the intestine to effort, but the intestine which would culminate in aggravation of the condition.

*Taxol* is not habit-forming. It readjusts the intestine to resumption of normal function unaided, thus is the biological nature of its action. It contains no irritant drugs of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation after a course of TAXOL, revert to normal regular peristalsis.

**"LACTOGEN"**

as easy to Assimilate as Natural Milk

The special Lactogen process ensures a product so closely akin to the characteristics of natural milk that not only are the proportions of its food elements practically identical, but the physiological character is also similar in every important factor. The fat globules, through homogenisation, are even smaller than those of breast milk, whilst the curd is just as light and flaky as that of the natural milk. For these reasons Lactogen is as readily digestible and as assimilable as Baby's natural diet—and the food you are safe in recommending in cases where breast feeding is inadequate or impossible.

## ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President THE MOST HON THE MARQUESS OF EXETER CMG ADC

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes are received for treatment. Careful clinical, biochemical, bacteriological and pathological examinations. Private rooms with special nurses male or female in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

### WANTAGE HOUSE

This is a Reception Hospital in detached grounds with a separate entrance to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological and pathological research.

### MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

### BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens and facilities are provided for handicrafts such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

## COURT HALL, KENTON, near EXETER,

for the treatment of eight Ladies, voluntary, temporary, or certified patients.

WERE RECEIVED AT

## The CLINIC in 1937

(236 were members of the Medical Profession  
or their dependents)

Being in effect Trustees for the Public of an Institution run in the interests of the Public members of the Company now operating The Clinic feel that the above figure of patients received during 1937 will be of general interest

The Nursing, Home, facilities and services are at the disposal of any Practitioner on the Register of the General Medical Council. In accordance with its Constitution the Company devotes the whole of its surplus revenue to improving the amenities and equipment of the Clinic. During 1937 a sum of over £5,000 was so expended on improvements in equipment, furniture and in the catering services. There is now a diet kitchen with a staff of fully trained dietitians. The nursing service, recently entirely reorganized, now comprises over 160 State Registered nurses. 3,004 operations were performed during 1937 in The Clinic's eight theatres. The room rates, which range from 10 guineas to 18 guineas (apart from a few suites at 25-42 guineas) average no more than 14 guineas. The Secretary will be glad to forward detailed particulars, and enquiries or visits from members of the Medical Profession are always welcome.

BRIGHTON EDUCATION COMMITTEE

ASSISTANT TO SCHOOL MEDICAL OFFICER AND ASSISTANT TO THE MEDICAL OFFICER OF HEALTH

Required to be qualified in the position of Assistant School Medical Officer (male or female). Candidates must not exceed 40 years of age.

## CITY OF CAPE TOWN TUBERCULOSIS OFFICER

Applications are invited from qualified medical practitioners not over 45 years of age for the position of Tuberculosis Officer in the City Health Department.

The position will involve such administrative, clinical, home visiting and other duties as may be from time to time prescribed.

The appointment will be terminable upon one month's notice on either side and is subject to the provisions of Provincial Ordinance No. 10 of 1912 (Cape) and amending ordinances and to the standing rules and regulations of the Council.

If the successful applicant is resident in the United Kingdom his first class fare from Southampton to Capetown will be paid and half salary during the voyage and he will be required to enter into a three years' contract with the City Council.

Salary will be at the rate of £800 per annum rising by annual increments of £50 to £1000 per annum and a motor transport allowance of £13 a month will be paid. The officer appointed will be required to devote the whole of his time to his office and not to engage in private practice.

Applicants must submit particulars as to age, qualification, present position and past experience with details as to experience in the diagnosis and treatment of tuberculosis and public anti-tuberculosis schemes, and must also submit a medical certificate of physical fitness. Applications, accompanied by copies of not more than three recent testimonials must be delivered in a sealed packet endorsed Tuberculosis Officer either to the undersigned or to Messrs Davis and Soper Ltd, 54 St Mary Ave London EC3 from either of whom also certain further particulars as to the position may be obtained on application. If candidates are resident in South Africa applications must be delivered to the undersigned not later than noon May 7th 1938. If candidates are resident in the United Kingdom applications must be delivered to the office of Messrs Davis and Soper Ltd not later than noon April 23rd 1938.

Applications should state when they can commence duty.

The canvassing of Councillors will be regarded as a disqualification.

FRANK G GALE  
Deputy Town Clerk

City Hall Capetown  
March 14th 1938

## COUNTY COUNCIL OF MIDDLESEX VISITING ANAESTHETIST

Applications are invited for the appointment of Visiting Anaesthetist at the COUNTY SANATORIUM HAREFIELD. Candidates must be medical practitioners devoting the whole or the major part of their time to anaesthetics and must be specially skilled in the administration of anaesthetics by modern methods to patients undergoing thoracic operations.

The officer appointed will be required to attend one session per week at a fee of £3 3s 0d per session. The appointment which does not carry any superannuation rights will be held during the pleasure of the Council and is terminable by one month's notice on either side.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials must be received by the undersigned not later than April 9th 1938. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed Visiting Anaesthetist Harefield.

Canvassing directly or indirectly will be a disqualification.

C W RADCLIFFE, Z  
Clerk of the County Council

Middlesex Guildhall  
Westminster SW 1  
March 17th 1938

## CITY OF NOTTINGHAM ASSISTANT MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE WORK

Applications are invited for the above post from women medical graduates experienced in practical midwifery and ante-natal and infant welfare work. The duties will be chiefly in the ante-natal and infant welfare clinics under the administrative control of the Medical Officer of Health.

Salary £600 p.a. by annual increments of £50 to £700. The salary is subject to deduction under the Superannuation Scheme of the Corporation. The successful candidate will be required to submit to a medical examination in and to reside within the City of Nottingham.

The appointment will be subject to one month's notice on either side.

Further particulars may be obtained from the undersigned and may be returned to the post before April 15th 1938. Canvassing will be a disqualification.

J E RICHARDS  
Town Clerk  
Nottingham  
March 15th 1938

## CITY OF LIVERPOOL CITY BACTERIOLOGIST'S DEPARTMENT

Applications are invited for a TEMPORARY JUNIOR ASSISTANT BACTERIOLOGIST in the above department. The appointment will be for one year. Candidates will be required to possess a registrable medical qualification and evidence of special bacteriological training is desirable. The salary will be at the rate of £400 per annum. The person appointed will be required to devote the whole of his time to the work of the department.

Applications accompanied by copies of three recent testimonials together with details of training, experience and research work should be addressed to the Town Clerk Municipal Buildings, Dale Street Liverpool 2 endorsed Temporary Junior Bacteriologist and be delivered not later than April 9th 1938.

Canvassing of members of the City Council will be regarded as a disqualification.

W H BAINES  
Town Clerk

March 21st 1938

## PORTSMOUTH EDUCATION COMMITTEE SCHOOL MEDICAL SERVICE

F E WARBRECK HOWELL  
Manchester 2 Town Clerk

March 28th 1938

## CITY OF NORWICH ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER etc

Applications are invited for the post of Assistant Medical Officer of Health and Assistant School Medical Officer to include the duties of Medical Officer with residence at the Isolation Hospital. Salary £600 p.a. annum (including emoluments valued at £150 per annum) rising by annual increments of £50 to £700 per annum. Board allowance at the rate of £60 per annum granted when absent from hospital on leave. The post is designated under the Local Government and Other Officers Superannuation Act 1922. For particulars apply to the Medical Officer of Health 68 St Giles Street Norwich by whom applications for the post must be received not later than April 11th.

## BRITISH POSTGRADUATE MEDICAL SCHOOL

Applications are invited for the post of FIRST ASSISTANT (non-resident) in the Department of Obstetrics and Gynaecology in the above-named School. Special experience in Obstetrics and Gynaecology is required. The post will normally be a full-time salary £250 to £400 according to experience and qualification.

Further particulars can be obtained from the Dean British Postgraduate Medical School, Deane Road, Shepherd's Bush, London W 12 to whom applications accompanied by two testimonials and giving the names of two referees should be addressed to a free post not later than the first post on Tuesday April 19th.

## LONDON COUNTY COUNCIL

Applications invited from medical practitioners of at least one year's standing to undertake a position. Experience in a resident appointment in a general hospital for at least six months desirable. Married quarters not available.

ASSISTANT MEDICAL OFFICER (Grade II) — Salary £350-£25 £425 with board lodging and washing.

(a) KING GEORGE V SANATORIUM near Godalming Surrey — Experience in pulmonary tuberculosis desirable.

(b) ST LUKES HOSPITAL Lowestoft Suffolk — Experience in non-pulmonary tuberculosis desirable. (No accommodation for a woman).

ASSISTANT MEDICAL OFFICER (Grade II) — Salary £250 a year together with board lodging and washing. Appointment for one year only in first instance (renewable for a second year under certain conditions).

(c) GROVE PARK HOSPITAL Lee S.E. 11 — Experience in pulmonary tuberculosis desirable.

(d) ST ALFEGES HOSPITAL 48 Vauxhall Hill Greenwich S.E. 10 — Casualty officer experience in anaesthetics desirable. (Candidates must have held resident appointment in a general hospital for at least six months).

Application forms obtainable (stamped address of footscap envelope necessary) from Medical Officer of Health Staff Division 2, County Hall S.E. 1 returnable by April 11th. Canvassing disqualifies.

## LONDON COUNTY COUNCIL CONSULTANT AND SPECIALIST SERVICES

APPLICATIONS INVITED for appointment as part-time CONSULTING PEDIATRIST for a total of one session a week for duty at Queen Mary's Hospital for Children, Carshalton Surrey and the Downs Hospital for Children, Sutton Surrey.

SALARY £125 a year (£75 a year if already employed as a part-time consultant or specialist in the hospitals service) and additional remuneration at the rate of £2 12s 6d a visit for emergency visits made in excess of the number of routine sessions.

Application forms containing full particulars obtainable (stamped addressed footscap envelope necessary) from Medical Officer of Health (Staff Division—6) County Hall Westminster Bridge S.E. 1 returnable by April 20th. Women eligible. Canvassing disqualifies.

## BOROUGH OF LLANELLY ASSISTANT (LADY) MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER

The Town Council invite applications for above whole-time appointment from duly qualified single Lady Medical Practitioners. Applicants must have had at least three years' experience in the medical profession and special experience in midwifery and child welfare work. Possession of the Diploma in Public Health will be an advantage.

Salary £500 increasing by annual increments of £25 to £700 per annum.

The Officer will be required primarily to carry out duties relative to Maternity and Child Welfare and School Children and any assigned work in connection with the Medical Services of the Borough under the directions of the Medical Officer of Health.

The appointment is subject to the 1922 Superannuation Act.

The selected candidate must pass a satisfactory medical examination.

Prescribed application forms may be obtained from the undersigned and when sent in should be endorsed Assistant Medical Officer and addressed so as to be delivered to the undersigned on or before April 20th 1938.

DAVID J PHILLIPS  
Town Clerk Llanelly

## LEICESTERSHIRE COUNTY COUNCIL COUNTY SANATORIUM AND ISOLATION HOSPITAL MARKFIELD (210 Beds) JUNIOR RESIDENT MEDICAL OFFICER

Applications are invited for the post of married male Junior Resident Medical Officer at the above Institution.

The appointment will be for a period of six months, renewable if satisfactory for a further six months.

The salary will be £300 per annum together with board residence and laundry. The person appointed will have opportunity of gaining experience in the treatment of tuberculosis and infectious disease and in X-ray work.

Form of application may be obtained from the undersigned and must be returned to the undersigned not more than three weeks before the closing date, April 15th 1938.

CLAUDE E RUMSEY  
County Council Clerk of the Council  
Leicester  
March 25th 1938

# HIS MAJESTY'S COLONIAL SERVICE

## COLONIAL MEDICAL SERVICE.

During 1938 the Secretary of State for the Colonies proposes to select a number of Medical Officers to fill vacancies the majority of which will occur in Tropical Africa and Malaya

**QUALIFICATIONS**—Candidates must be British subjects of European parentage under 35 years of age and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments or who have special knowledge of anaesthetics radiology surgery medicine ophthalmology gynaecology and midwifery diseases of the ear nose and throat venereal diseases etc

**SALARY**—Initial salaries vary from £600 to £700 and rise by increments to a maximum of between £1 000 and £1 200

**PRIVATE PRACTICE**—Private practice is not allowed as of right but in the case of some appointments it is permitted on certain conditions

**QUARTERS**—In Tropical Africa, free quarters or an allowance in lieu are provided. In Malaya quarters are provided at an annual rental not exceeding 6% of the officer's salary

**PASSAGES**—Free first class passages are provided on first appointment and when proceeding or returning from leave. Assistance is also given towards family passages

**TERMS OF APPOINTMENT**—The appointments are pensionable subject to a probationary period which varies from two to three years

**COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE**—Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas

**DUTIES**—Although Medical Officers are appointed in the first instance for general service there are opportunities for work in special branches of medicine and surgery in public health and in medical research

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 8, Buckingham Gate, London, S W 1

# ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in July, 1938

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty

At the end of three years' service, officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax)

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations and to obtain further qualifications

Copies of the regulations for entry and conditions of Service, including rates of pay, allowances and retired pay may be obtained from the Medical Director General of the Navy, Admiralty, S W 1, and from the Deans of all Medical Schools

Applications for entry from intending candidates must be received not later than 31st May, 1938

## BOROUGH OF TORQUAY

### APPOINTMENT OF DEPUTY MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER

Applications for the above position are invited from registered medical practitioners not exceeding 40 years of age if occupying a designated post under another local authority but otherwise not exceeding 35 years of age and possessing a Diploma in Public Health or a similar qualification.

The officer appointed will be required to devote the whole of his or her time to the duties of the office and must not engage in private practice.

The salary will commence at £600 per annum rising subject to satisfactory service by annual increments of £25 to £700. A car allowance of £40 per annum will be made.

The position will be subject to the provisions of the Local Government and Other Officers Superannuation Act 1922 and the successful candidate will be required to pass a medical examination.

Lists of duties and forms of application may be obtained from the undersigned and the forms duly completed must be returned in an envelope endorsed Deputy Medical Officer of Health not later than April 20th 1938.

HERBERT A. FIELD

Town Hall Torquay

Town Clerk

March 29th 1938

## CITY OF LEICESTER

### ISOLATION HOSPITAL AND SANATORIUM (340 Beds)

#### DEPUTY MEDICAL SUPERINTENDENT

Applications are invited from registered Medical Practitioners (male) for the post of Deputy Medical Superintendent at the above Hospital.

Applicants should be unmarried and preference will be given to those who have held General Hospital appointments together with experience in either Pulmonary Tuberculosis or Infectious Diseases.

Commencing salary £400 per annum rising by annual increments of £50 to £600 per annum together with residential emoluments valued at £150 per annum.

The appointment which will be in the first instance for a period of two years is designated under the Local Government and Other Officers Superannuation Act 1922 and is terminable by three calendar months notice on either side.

Further particulars of the appointment and forms of application can be obtained from the undersigned. Applications to be accompanied by copies of not more than three recent testimonials and must be delivered not later than April 14th.

E. K. MACDONALD

TORONTO

CALCUTTA

Mr A. LAWRENCE ABLL, F.R.C.S., writes

This proctoscope, a modification of the already popular Clifton's proctoscope, has been in use for two or three years, and has proved very satisfactory. The chief points about it are:

It is long enough to allow a complete inspection of the mal canal in the fattest patient.

The tenestrum occupies about one-third of the circumference of the distal third of the instrument. This allows the careful inspection of approximately one quarter of the mal canal, and, at the same time, keeps the remainder of the passage away from the part under examination.

Its passage is completely guided and rendered quite smooth by a well-fitting obturator.

Its proximal end is wide enough to allow clear vision, and the easy insertion of instruments, needles, etc.

Its handle carries a light, which shines into the lumen of the proctoscope, and does not confuse the eye of the examiner.

Its interior is dulled, giving no reflection from the walls but an excellent view of the pile-bearing area.

The whole is easily cleaned. It is fitted up and taken to bits in a second, and has proved a most useful instrument. It is strongly and lightly made with a good finish by Messrs Down Bros.

*Vide Brit Med Jour, 26th June, 1937*

## AUTOMATIC ANAESTHETIC APPARATUS

for use in Midwifery and for General Anaesthesia

Designed by T. YOUNG SIMPSON

IMPROVED MODEL

The apparatus illustrated can be safely used for Analgesia or Anaesthesia during labour, or for Anaesthesia during any surgical procedure with or without a pre-anaesthetic. A Surgeon writes: "The apparatus was designed for PRODUCING PAINLESS LABOUR, and none of the patients on whom I have used it remember anything of the labour afterwards. I have not found it check the pains or prolong the labour. It can safely be left in the hands of a nurse under medical supervision."

# FOR CASES OF MOVABLE KIDNEY

where need of support is indicated

Spencers are individually designed for each patient to support the abdomen from below upward and backward and to place the pull of the abdominal support on the pelvic girdle not on the spine at, or below, the lumbar region

An abdominal support to assist in the retention of a movable kidney must not perfectly reach from the iliac bone to the umbilicus, and stay in place continuously.

A Spencer Belt or Supporting Corset meets these requirements to a high degree of perfection because each garment is a special creation designed and made from the actual measurements and posture description of the patient.

Spencer Supports are individually designed for Back Conditions, Hernia, Sacro-iliac Strain, Enteritis, Stasis of Intestinal Stasis, Movable Kidney, Pregnancy and Prolapsed Rectum.

They are liked by patients because their surgical features are embodied in a style corset which saves the expense and discomfort of purchasing and wearing two garments. They improve appearance, are light in weight, comfortable, flexible and easily laundered.

Each Spencer is designed to improve posture and is guaranteed NEVER to lose its shape.

**BEWARE OF SUBSTITUTION**—Spencer Corsets Ltd. are the only makers warning the medical profession that in several instances where doctors have specifically prescribed a Spencer Support, a corset of a different make has been substituted and because its makers do not understand the Spencer principle of individual designing has been unsatisfactory. Every genuine Spencer Support bears the SPENCER Label.

Spencer Supporting Corset shown open revealing abdominal supporting section. Shadow graph indicates kidney pad which is provided when prescribed by doctor. The side tapes of this inner support slip through the outside of the garment which is a separate section.

Trained Spencer Corsetters are resident throughout the Kingdom. Name of nearest gladly supplied on request.

Identically trained Spencer Corsetters all at our service for your patient's health and comfort.

## CASE RECORDS

### *The value of artificial limbs for children*

THE child who attends school on crutches or a Pylon is a cripple, and as such he is necessarily separated from his fellows and develops a crippled mental attitude. His physical growth is seriously interfered with, particularly in cases where only one crutch is used. Here the full weight of the body is borne on one leg at every step, and the Pelvis is tilted downwards on the unsupported side. Scoliosis is inevitable result. In addition, the shoulders are hunched, the chest contracted and the free use of the arms impeded. At the same time the muscles of the stump atrophy, and there is abduction and flexion with loss of mobility.

The use of a Pylon does not give much better results. The lack of a correctly articulated foot means loss of support, and the difficulty of balancing on a Peg-end results in the body being thrown sideways at every step. The absence of a knee joint forces the patient to swing the Pylon from the hip in a circular movement, and once this habit is formed it is impossible to teach a patient to walk correctly on a fully articulated limb.

Of the number of children who have passed through our hands some were so young when fitted that they actually took their first steps on artificial limbs, and were thus spared the misery and loneliness of a cripple. A child learns to use a limb so quickly and well that in a very short time he is no longer regarded as a cripple but begins to live the life of a normal child. He is able to join freely in the work and play of other children, both at home and at school, even participating in school games; in fact, it would be difficult to exaggerate the improvement in health and happiness of a child after the fitting of a limb.

It is almost inconceivable that after seeing both sides of the picture there can be any hesitation in providing artificial limbs for amputated children.

#### Case No 7641 1929

Amputation double Symes Cause Deformed feet with absence of fibulas (congenital)

The limbs were amputated when the child was six years old, and both stumps were fully end-bearing. As is common in these cases, there was excessive lateral movement of the knee joints, particularly in the left leg, which showed marked Genu Valgum when the patient was bearing his own weight. (See Fig No 1)

After careful consideration it was decided to construct a pair of light metal limbs with extensible shins to allow for growth, and the stumps being fully end-bearing the sockets were fitted loosely, leaving

room for expansion. At the same time the Genu Valgum deformity of the left leg was corrected. (See Fig 2)

The child made very rapid progress and was soon able to walk quite naturally, run and jump, ride a two-wheeled bicycle, and take part in most of the school games. The improvement in his health, mental and physical, has been most striking. A second pair of limbs was made 2½ years later, and Fig Nos 3 and 4 show the child at the age of 11, when a third pair of limbs was made. Comparison with Fig No 1 will show the increase in the size of the stumps and the muscular development of the thighs. There is practically no Scoliosis or Lordosis.

## INTESTINAL TOXAEMIA

More and more doctors are prescribing Salvitae to correct faulty elimination and toxic retention. Salvitae combats acidosis and restores the alkalinescence of the circulating fluid.

# SALVITAE

SALVITAE stimulates and encourages the natural activity of the several eliminative organs with the object of dispersing and excreting the toxic elements formed through dietetic errors and imperfect metabolism.

*Professional samples and literature gladly sent on request*

COATES & COOPER LTD, 94, CLERKENWELL ROAD, LONDON, EC 1

## 'PANOPEPTON'

### THE FOOD FOR THE SICK

Supplies directly available energising food, especially designed to make no draught upon the strength of the enfeebled organism.

PANOPEPTON contains, in stable agreeable solution, 24% of solids, derived by physiological hydrolysis from prime lean beef and whole wheat in a scientifically balanced ratio.

'PANOPEPTON' has nourished and restored in many cases where the patient has steadily lost strength on other foods.

*Supplied in 12-oz bottles*

## 'ENZYMOL'

### A SURGICAL SOLVENT AND ANTISEPTIC

AN EXTRACT OF THE GASTRIC GLAND OBTAINED BY DIRECT SOLUTION, ESPECIALLY PREPARED FOR EXTERNAL APPLICATION.

ENZYMOL exerts remarkable solvent healing antiseptic and deodorizing action in the treatment of pus cases in general, gangrene abscesses, sinuses, leg ulcers, etc etc.

*Supplied in 4-oz bottles*

## AN AID TO HEALTHY DEVELOPMENT

**M**ODERN medical research makes it increasingly clear that abnormalities of form, mental defects and even permanent constitutional weakness, are often a direct result of failure to obtain in infancy a diet adequate to the physiological needs of the organism. The basic necessity, therefore, in constructing the dietary of the infant and growing child, is to ensure one that is complete in all the essential food elements.

"Ovaltine" finds one of its most valuable applications in this direction. Composed of the nutritive constituents of fresh, full-cream milk, eggs and malt, in well-balanced proportions, it supplies calcium, phosphorus, vitamins and other accessory food factors and its regular addition to the ordinary diet of the child renders this safe and adequate.

"Ovaltine" is so delicious and easily digested that it can be prescribed with complete confidence for children of all ages. "Ovaltine" is easily prepared and is most economical.

BRAND OF IODISED OIL B P

*The ideal contrast medium for X-ray diagnosis*

Iodatol is an iodine addition product of poppy-seed oil containing 40% of combined iodine, it conforms in every way with the specification laid down for Iodised Oil of the B P Addendum. Iodatol is employed as the routine method of investigating the cavities of the body radiographically.

As a contrast medium for the investigation of the bronchial tree, the Fallopian tubes and uterus, the paranasal sinuses, the spinal column, and for the exploration of abscesses and fistulæ, it is unsurpassed.

AN IMPORTANT INVESTIGATION INTO

# The Cost of treating HYPOCHROMIC *anæmia*

"With regard to cost, ferrous sulphate tablets 'Glaxo' (Fersolate Tablets) have an obvious advantage whether used in private practice or in hospital."\*

The above conclusion is stated in a paper published in the March issue of the Edinburgh Medical Journal (1938, 45, 193) dealing with the potency of various preparations of iron.

Ferrous salts were found to show from 5 to 9 times as great a utilisation as scale preparations when optimal dosage of both types of iron preparation is employed.

Each Fersolate Tablet contains 3 grs. exciccated ferrous sulphate, the haematinic action of which is assisted by the incorporation of copper and manganese in the Fersolate formula. By prescribing Fersolate Tablets (2 to 3 daily) effective iron therapy is achieved at a cost of *less than a penny a day*.

It may be concluded that 9 grains of ferrous sulphate containing 180 mg. metallic iron is certainly as efficacious as 90 grains of iron and ammonium citrate containing 1215 mg. iron. ★ Davidson L.S.P., Fullerton H.W., Edin. Med. J. 1938 45 210

—the new SELF-ADHESIVE BANDAGE that adheres to itself but not to the skin or hair.

BACKED BY FORTY YEARS' EXPERIENCE IN THE MANUFACTURE OF HIGH GRADE SURGICAL DRESSINGS

This new type of bandage is made from a pure Surgical Cotton Gauze of high quality, treated by a special process which renders the material self-adhesive, whilst at the same time non-adhesive to other substances. The materials used in manufacture are entirely harmless and cannot cause irritation to the skin.

- 1 It provides the easiest possible method of bandaging. Simply roll the bandage round and press the end down. It is then firmly fixed. No pins or other fastening necessary.
- 2 It is equally easy to remove. Find the end and unroll. The bandage will come away cleanly without discomfort to the patient.
- 3 For most purposes very much less material is necessary. Also less is wasted as the beginning of one bandage can readily be affixed to the end of another.

- 4 While the material admits air, thus assisting in the healing process. It resists water and is not removed or disturbed while washing.
- 5 The bandage gives a degree of support quite impossible with the ordinary type. This applies particularly to wrist and ankle sprains where, owing to the property of self-adhesion, fewer turns are required yet far more support is provided. Eminently suitable for splint work.
- 6 Owing to the neat finish of the bandage after application, the patient can frequently resume work at once with comfort and safety.

# TWO CHOLINE COMPOUNDS FOR PARASYMPATHETIC STIMULATION

## 'DORYL'

(Carbaminoylcholine chloride)

A stable and potent choline ester greatly superior to acetyl choline. Very effective by injection in post-operative retention of urine and intestinal atony, paralytic ileus etc. Oral doses possible and successful in irritable hearts, paroxysmal tachycardia and anxiety neurosis. Raynaud's disease and certain other vascular diseases have benefited by Doryl administration. In ophthalmology a special Doryl solution has proved useful in glaucoma. For tobacco and other amblyopias the tablets have been found valuable. A special solution is also available for the treatment of ozaena.

TABLETS — AMPOULES — SOLUTIONS

## 'MECHOLYL'

(Acetyl-beta-methylcholine chloride)

Mainly recommended for use by iontophoresis and has proved very effective in treating arthritis especially of the rheumatoid type, peripheral vascular diseases such as Raynaud's disease and scleroderma, thrombo-angitis obliterans, and ulcers. A 0.1-0.5% aqueous solution with a strength of current of 20-30 mA is advised.

**GENATOSAN LTD., LOUGHBOROUGH.**

**DOSAGE** For children and adults two teaspoonfuls three times daily or according to circumstances For infants 1 teaspoonful added to each bottle feed

# DIPHTHERIA PROPHYLACTIC

*Purified Toxoid with Aluminium Hydroxide  
and*

*Purified Toxoid in Isotonic Solution*

*for use by the method described by Claus Jensen*

This Diphtheria Prophylactic consists of a toxin which has been detoxicated by means of formaldehyde and heat. It has been subjected also to a process of purification by means of which most of the non-specific proteins, salts and other inert substances present in the crude toxoid have been removed. Before distribution, the purified diphtheria toxoid is mixed with a sterile suspension of aluminium hydroxide.

The recommended dosage is a single injection of 1 c.c. of a purified toxoid with aluminium hydroxide, followed four weeks later by nasal instillation of the 'purified toxoid in isotonic solution'. Such instillation does not in any way trouble the children and may well be carried out by the mother or visiting nurse.

It has been found that while in the majority of cases a single injection will render children immune against diphtheria, in some cases a second, and even a third, injection is necessary. The nasal instillation of purified toxoid in isotonic solution has been found to be an effective substitute for the second and third injections.

Diphtheria Prophylactic is issued in sets, each set containing

1 c.c. ampoule of purified diphtheria toxoid with 10 per cent. aluminium hydroxide (for injection)

2 c.c. vial of purified diphtheria toxoid in isotonic dilution (for instillation)

1 nasal dropper

# WHY AGAROL BRAND COMPOUND FOR CONSTIPATION ?

Among the curative measures advocated for overcoming constipation, none has proved more consistently successful than AGAROL—the original emulsion of mineral oil and agar-agar with phenolphthalein. Agarol renders the faecal mass plastic and pliable with unabsorbable moisture. It lubricates the intestinal tract and

gently stimulates peristalsis, ensuring an easy and complete evacuation.

Used over a reasonable period, Agarol gradually restores muscular tone and functional activity of the bowel, with the gratifying assurance that natural evacuation will follow without the need for further medication.

# CRUNCHY FOODS AND THE DIGESTION

---

It is generally recognised by dieticians that hard foods are more easily digested than soft ones. The explanation commonly advanced is that soft foods are often swallowed in insufficiently chewed masses, whereas hard foods cannot be swallowed until they are properly broken up by the teeth, and in consequence the digestive juices have a larger surface area to work upon and their action is more effective.

Many physicians therefore recommend that the normal diet should contain a fair proportion of hard, dry food. They find that Ryvita, eaten regularly with meals, supplies a valuable factor in which the modern diet is otherwise deficient. Free samples of Ryvita for distribution to patients will gladly be supplied on request.

Metaphedrin Inhalant No 99 offers, in a light bland mineral oil solution the shrinking and decongesting effects of Ephedrine alkaloid 0.95%, and the powerful antiseptic properties of Metaphen 1:2500. Sprayed or dropped into the nose, this Abbott Inhalant not only relieves pain and congestion caused by head colds, hypertrophic rhinitis, hay fever and nasal or sinus infections, but also provides a potent agent to combat infection. Metaphedrin Inhalant No 99 is also of great value as a preventive of infection and, when used at the very onset of certain cases, often shortens the

course of the disease itself • An important advantage of Metaphedrin Inhalant No 99 is its very low surface tension which results in an increased miscibility with the aqueous nasal secretions. A special dye developed in the Abbott research laboratories protects the Ephedrine alkaloid content of the preparation against the decomposing effect of light • Metaphedrin Inhalant No 99 is supplied in 1/2-ounce 1-ounce 4-ounce and 16-ounce bottles as well as in convenient Atomizer Outfits in which

a 1 pound bottle of M tape drive La  
halant No 99 is offered in kind as a  
with a compact atomizer. • Reputations

## In Pruritus Ani,<sup>1</sup> Anal Fissure,<sup>1</sup> Pruritus Vulvæ,<sup>1</sup> and Lower Abdominal Pains originating from the Cervix Uteri<sup>2</sup>

Proctocaine is a lasting, non toxic, local anæsthetic, for use in irritating or painful conditions of the skin and subcutaneous tissues. It is an improved form of ABA. Proctocaine is a combination of oil soluble anæsthetics of low toxicity. These are combined so as to produce immediate local anæsthesia which is maintained by the slow, uniform absorption of its oily vehicle, and action of its oil soluble ingredients.

The advantages of Proctocaine over other solutions have been found<sup>1</sup> to be as follows

- 1 Its effect is almost certain
- 2 It produces anæsthesia or hypo anæsthesia for periods varying from 7 to 28 days or longer
- 3 The relaxation which it produces in the anal musculature is much greater and more prolonged
- 4 It is comparatively non toxic, injection of 20 to 30 ccm producing no general effect
- 5 Even large quantities of it at one sitting have not been found to produce any local reaction if injected properly
- 6 Its injection is painless if made slowly
- 7 In no case did it produce severe after pain

## MANDECAL

(Compound Calcium Mandelate B D H)

The value of Mandecal in the treatment of urinary tract infections was demonstrated in an investigation reported recently (*Lancet*, February 26, 1938, p 494). The results, summarised in the accompanying table, show that of the 33 patients treated with Mandecal 75 per cent were cured. Further, only four of them needed ammonium chloride in order to render the urine acid and, of these, two probably had some renal dysfunction which prevented the production of adequate acidity, finally, the conclusion was drawn that Mandecal provides the most pleasant form of administering mandelic acid.

# Supplements to Children's diet

## The Effect of Adding Vitamin B

A recent editorial statement in the *British Medical Journal* (16th October, 1937, page 753) that "Vitamin B<sub>1</sub> deficiency [is] an outstanding fault in the diet of many millions of people" lends additional significance to the results of a test carried out with the co-operation of a large group of doctors before knowledge of Vitamin B deficiency had reached its present state. The test was devised to ascertain the effects of the addition of Vitamin B to the diet of children, even in cases where reliance had been placed on an "ordinary mixed diet" as guaranteeing a suitable supply of Vitamin B.

The children were placed in two age groups, namely, 1-5 (infancy) and 6-15 (the chief period of growth). The main criteria employed were:

- (1) Improvement in appetite (loss of appetite is known to be characteristic of Vitamin B<sub>1</sub> deficiency)

- (2) General physique (3) Bowel function  
(4) Apparent strength and resistance

Of the 158 children in the first group, 141 (89.2%) were classed as "definitely improved" and 17 (10.8%) were classed as having shown no definite response. In the second group, out of 178 children, 176 (98.9%) were rated as "definitely improved," while only two in this group showed no definite response. It was considered significant that in the second group definite improvement in health followed in practically all cases as shown, whereas in the first group there was a small but definite minority of children who showed no improvement in health. This disparity is possibly connected with a special need for increased supplies of Vitamin B during the years of maximum growth. The results are set out more completely in the following table:

	GROUP I		GROUP II	
	141 Children ages 1-5		176 Children ages 6-15	
	No. of cases	Per cent	No. of cases	Per cent
Improvement in appetite	52	36.9	50	28.4
Improvement in physique	58	41.1	77	43.8
Improvement in bowel function	38	26.9	43	24.4
Improvement in digestion	5	3.5	5	2.8
Diminution in symptoms associated with constipation e.g. head ache, listlessness, etc.	2	1.4	10	5.7
Improvement in strength, resistance, etc.	23	16.3	39	22.2

The Vitamin B supplement employed was Bemix which supplies, in addition to approximately 100 International Units of Vitamin B<sub>1</sub> per ounce, all the other vitamin and mineral constituents of wheat germ, some at least of which are regarded as essential to optimal nutrition. Clinical sample of Bemix and literature on request. The Bemix Laboratories (Dept. B 37), 23, Upper Mall, London, W 6.

LABORATORY NATIVELLE LIMITED  
NORTH CIRCULAR ROAD, LONDON, N W 2

BY  
R W JOHNSTONE, CBE MD, FRCS Ed, FCOG  
Professor of Midwifery and Director of Women's University of Edinburgh

The train of my thought on this subject was started by reading about a year ago a brief and modest article in the *American Journal of Obstetrics and Gynecology* in which Drs Allen and Bauer of Chicago summarized an analysis of 9 696 consecutive uterine pregnancies in their hospital service. Their conclusions were statistically tabulated but they were also put into words which arrested my attention like a slogan. Thus (1) It was five times more dangerous for a woman affected with a medical disease to bear children than it was for a healthy woman (2) A child born to a woman suffering from a medical disease was twice as apt to be stillborn as a child born to a healthy mother

This raised the question in my mind whether the association of general diseases with pregnancy was as significant a factor in relation to maternal mortality and morbidity in this country. I knew of no statistics comparable to those of Drs Allen and Bauer because while in American cities almost every woman goes to hospital for her confinement and their statistics of a consecutive series of cases may therefore be regarded as a very fair sample of the population in this country the patients who go to the maternity hospitals are still only a variable proportion

These reports together cover some 810 deaths, of which just under 25 per cent were attributed to obstetric diseases rather than to an obstetric factor. In view of this I sought information from the Department of Health for Scotland kindly gave me, and the first place Dr Charlotte Douglas occupies in the schedules concerning maternal death in Scotland has occurred since the 1955 report was drawn up. Of 2136 deaths she attributed 561—that is 26 per cent—to associated diseases. I regard this as probably too high an estimate but it must be remembered that in making such an analysis there is a large personal equation and that the schedules are often so sketchily filled up that in many cases more than one opinion might well be formed as to the primary cause of death. In the second place Dr Lang also analysed the deaths in the Registrar General's Hospital Edinburgh in the year 1954, and found a total of 462 she attributed 145 or 31 per cent to associated diseases.

The death of the mothers in these cases is not the only tragedy; there is also the comparison of the fatal pregnancies in our words, the effect of the pregnancies upon the health of the mothers. The English report is a corollary to the case of the non-tubercular disease and kidney disease.

The death of the mother is also the cause of the tragedy, there is also the fact of the fatal pregnancies or upon the fact of diseases upon the pregnancies or the cause of child if born alive is the corollary to the fact of pregnancy upon the disease. The English report gives no information on this important point but in the 1935 Scottish report covering over 2000 maternal deaths we found that in only 40 per cent was the child born alive. In the other 60 per cent the mother had died undelivered or before her death had aborted or had been delivered prematurely or had given birth to a still

4031

born child or to a living child which had not survived for more than a comparatively few days. That figure, of course, includes a very large number of obstetrical emergencies, and is not confined merely to cases of associated disease. But if we confine our attention to the latter and choose the main disease groups we obtain these figures:

Maternal Deaths due to	Fœtal Deaths
Heart disease	59 per cent
Non tuberculous respiratory disease	70 "
Renal disease (including pyelitis)	68 "
Tuberculosis	55 "
Anæmia (" + malnutrition)	42 "

The corresponding figures for the 2,136 maternal deaths in Scotland investigated since 1935 showed

Maternal Deaths due to	Fœtal Deaths
Heart disease	65 per cent
Non tuberculous respiratory disease	57 "
Renal disease (including pyelitis)	60 "
Chronic and acute nephritis alone	76 "
Anæmia, malnutrition, debility	46 "
Tuberculosis	60 "

From the humane point of view this aspect of the problem is perhaps less important, but from the national standpoint in these days of a falling birth rate it is very significant.

Now it is obvious that to analyse any number, however large, of maternal deaths is by no means an accurate method of assessing the actual incidence of associated diseases, because it takes no cognizance of the patients who suffer from these diseases but survive. There is, so far as my knowledge goes, no accurate means of assessing the actual incidence of associated diseases in pregnancy, and I can present no figures parallel to those of Allen and Bauer. An attempt was made to gain some knowledge on this point in connexion with the investigation on which the 1935 Scottish report was based, for in the course of their analysis of the mortality figures the investigators felt that "much of the information could not be fully used without comparable details for mothers who survived. Accordingly an inquiry into the circumstances attendant upon all births in Scotland over a period of six months was instituted. It was purely voluntary, and the schedules were completed by the doctor or midwife. The returns, which were in many respects incomplete and imperfect, covered 39,205 births, and one rough conclusion which may be drawn is that in 10 per cent of the mothers there was a definite deterioration in health during pregnancy, most of which was attributable to the coexistence of general diseases. How far this deterioration was permanent I have no means of knowing.

These morbidity figures for Scotland showed that the proportionate incidence of the more important disease groups was parallel to their proportionate roles in the mortality figures, with the striking exception of heart disease. Thus the incidence of non-tuberculous respiratory disease (including in order of frequency influenza, bronchitis, asthma, and pneumonia) was 3 per cent, that of kidney disease 3.3 per cent, and that of heart disease 0.9 per cent. It is surely a very striking commentary on its dangers that heart disease should be below 1 per cent in its incidence in over 39,000 pregnancies in Scotland, and yet in both the English and the Scottish reports should be found responsible for over 49 and 75 per cent respectively of the total maternal deaths from all causes, both obstetrical and medical, and in each series for about 25 per cent of the deaths attributed to associated diseases.

So much, then, for the importance of these associated diseases in pregnancy. I have tried to show that they

account for something between one-quarter and one third of maternal deaths, and that in those mothers who survive they cause definite ill-health in some 10 per cent of cases. Lastly, they are accountable for a huge wastage of foetal and neo-natal life.

### Some Interesting Problems

My next point is that the association of medical diseases and pregnancy presents us with some peculiarly interesting problems. Disease means that some organs are partially disabled. Pregnancy means that increased demands are put on all the mother's organs. Therefore, if pregnancy occurs in a woman who is already suffering from disease, it superimposes conditions of strain upon already disabled organs, while if disease originates after the pregnancy has already begun it introduces an element of disability to the pre-existent conditions of strain. Further, it may be assumed that the pregnancy-strain element is capable of being assessed with some approach to accuracy, while the influence of the disease is generally less capable of measurement. We are therefore dealing with the interaction of two sets of factors—one more or less known, the other more or less unknown—and the situation partakes of the character of a clinical experiment. To watch how the diseased organs behave under the new conditions becomes a fascinating study, while to determine whether the experiment may safely be allowed to continue or whether and just when it must be interrupted calls for the exercise of a wide knowledge and a nice judgment.

It is not necessary to recall to your recollection all the physiological changes in the maternal organism produced by pregnancy. The fact that only the woman of perfectly sound health of body and mind can adapt herself to the new conditions without suffering from some symptoms of difficulty is familiar to us all, as is also the significant fact that such a woman feels triumphantly and exuberantly well during pregnancy, presumably because all her organs are working under high pressure, so to speak, yet without undue strain. But so complex is the necessary adaptation that if disease exists the affected organ is liable to suffer further detriment, while in other cases an occult weakness may become revealed for the first time during pregnancy. May I try to illustrate my thesis by one or two examples?

### Cardiac Disease

Consider, for example, diseases of the heart, most commonly chronic endocarditis of rheumatic origin. For my purpose it matters not what the exact nature of the heart lesion is, nor even whether the organic defects are or are not fully compensated. The point is that soon after pregnancy begins the heart enters upon a period of progressive strain which may last for several weary months and culminate in the severe muscular effort of labour.

That the normal heart is able to bear the strain of pregnancy and labour is obvious, and I do not suppose that with healthy patients we often give any thought to the matter. But that astute and painstaking observer the late Sir James Mackenzie has told us that even the healthy heart does give indications of the strain of pregnancy. Probably all of you who are especially interested have read his classical monograph on *Heart Disease and Pregnancy*—a little book which is full of wisdom of a much wider application than its immediate subject, salted with devastatingly candid criticisms of both obstetricians and physicians. That sagacious old Scot, in some respects so reminiscent of Thomas Carlyle, based his statement characteristically on his own personal observation of such signs as the restriction of the response to effort, on the

slight tendency to oedema at the bases of the lungs recognizable only on careful auscultation on the tendency to overfilling of the veins of the lower limbs and on the pulsation of the jugular veins. He summarizes his views in these words. It is perfectly evident that in the pregnant state towards the later months the heart is embarrassed in healthy women for the woman is not capable of so much exertion as she was accustomed to undertake and becomes breathless during efforts which at other times would not have inconvenienced her. If we accept Mackenzie's statement then *a fortiori* the diseased heart is bound to manifest more obvious reactions to the same conditions and it is the detection and proper evaluation of these that is the practical problem.

Now it is no part of my purpose to discuss the methods of detecting incipient heart failure or preventing its development or of treating it when once declared. These points are familiar to you all. I would however just summarize the experience we have had in the Royal Maternity Hospital Edinburgh where Dr Rae Gilchrist acts as our advisory physician. On the whole that experience in the last twelve years has tended to imbue us with a tempered optimism provided we get these patients under our supervision early in pregnancy. For we never see in such women the advanced degree of congestive heart failure often found in women admitted as emergency cases later in pregnancy. This is obviously a point of very wide application for if congestive heart failure can be avoided by adequate treatment and supervision under the conditions or strain imposed by pregnancy then all the more can similar care avert heart failure in non-pregnant patients. Dr Gilchrist attributes such success as we have achieved to prolonged rest in bed to the use of large doses of digitalis on modern lines and to the exhibition where necessary of the extraordinarily efficacious diuretics of the mercurial type such as salyrgan neptal and novurate.

A second point is that the study of heart disease in pregnancy demonstrates impressively the enormous power of even a damaged heart to adapt itself to a gradually increasing burden and even to post-operative shock and anaesthesia provided congestive failure is not present. The key to that statement surely lies in the words "a gradually increasing burden" for it is a physiological truism that all our organs have an amazing power of adaptation provided the stress is applied gradually.

Thirdly we have been impressed with the utility of any operative procedure in the presence of congestive heart failure. It is the straw that breaks the camel's back. As our experience has increased we have found ourselves gradually doing fewer Caesarean sections in heart cases because we have seen that ordinary labour is surprisingly well borne. The labours of cardiac patients are indeed often remarkably and inexplicably easy. A fair proportion of them occur prematurely and in these the small size of the baby makes for an easy labour. But even at full time the labour is often unexpectedly easy.

Fourthly the danger is not always completely over when the labour is passed. In patients who have shown any pronounced degree of heart failure before labour exhaustion of the cardiac reserve sometimes occurs suddenly and totally a few days later. Care must therefore not be relaxed.

Fifthly it is remarkable how slight is the embarrassment induced by pregnancy in cases of congenital heart disease. This teaches us that the prognosis must be better for such of these individuals as reach puberty than might be supposed. Congenital cases are but a small percentage

of the total coming under observation in any ante-natal clinic but we have not seen one go on to an sign of congestive failure. This contention is to some extent supported by individual cases reported in the literature—for example Firket's patient a woman with combined mitral stenosis and auricular septal defect who had eleven uneventful pregnancies and three abortions and lived to be 74 years of age.

Lastly our experience seems to show that death from congestive heart failure in young or middle aged married women could be prevented or postponed if after one or two pregnancies more of them were sterilized. It is infrequently happens that having sustained one or two pregnancies successfully a woman after an interval of some years during which in all probability conception has been practised presents herself at the hospital about the sixth month or later with early signs of congestive failure. Such cases do badly. Sterilization earlier might well have prolonged the life of such a patient.

### Anaemia

I turn next to anaemia as a subject in which medicine and obstetrics have found much common ground in recent years and in which the contact has been the means of considerably advancing knowledge. The fact that tissues of women in pregnancy are unduly filled with fluid has long been observed and the old clinicians used to attribute it to what they described as the venous congestion of pregnancy.

When the study of the blood began to be placed on a scientific basis it was recognized that in pregnancy there is an increase in the quantity of the body fluids but due not strictly to plethora but rather to a dilution of the blood by an increase in its fluid constituents. In recent years numerous observers have carried out repeated systematic observations of the blood of pregnant women at frequent intervals throughout the whole period of gestation and the puerperium and from these observations it appears that there is uniformly a definite fall both in the number of red cells per cubic millimetre and in their haemoglobin content. This fall begins at the end of the third month reaches its lowest point at the seventh month and persists to the end of the eighth month when conditions usually improve. Within a few days after delivery there is a rapid improvement and continues during the next few months and by six months after delivery the blood should be once more in a normal condition.

We have also come to appreciate in recent years how very real are the demands which the upbuilding of the foetus makes upon the mineral constituents of the maternal blood through the placental interchanges and how often the mother's blood contains an inadequate supply of these substances her blood and tissues will become depleted or them to an extent which may cause more or less serious symptoms. The harmonious symphony which nature said to describe the relation of mother and foetus in a healthy pregnancy under perfect hygienic conditions degenerates into something indistinguishable from parasitism in the undernourished mother. The normal demands are for iron, calcium and phosphorus. The possible depletion of the mother's blood is well known with the disease of osseous metastasis. The more recent has been considered as a possible explanation of the inertia in labour. It is possible that upon the mother's resources the foetus remains until calcium and phosphorus the result is seen in a predilection to

rickets after birth. But in relation to anaemia our main interest is concerned with iron, for while there is no direct transference of blood from the mother to the foetus, yet the latter has to derive from the former the materials for making its own haemoglobin. This, as Strauss and Castle point out, means the equivalent of a definite blood loss in every pregnant woman, even in the absence of any actual haemorrhage. Moreover as the same authorities have proved, "no matter how anaemic the mother, the infant is born with a normal amount of haemoglobin."

Bunge has shown that the milk of a bitch contains the same quantities of mineral substances as the tissues of its offspring except iron, which is present in the tissues of the offspring in a quantity six times greater than in the mother's milk. This store of iron gradually diminishes during the period of lactation, but increases again when the young animal begins to take a mixed diet. In other words, the offspring has a store of iron at birth for the purpose of supplying that substance during the weeks in which it is fed on its mother's milk, which is poor in iron. Hugounenq confirmed these findings in general with regard to the human foetus. Weight for weight the liver of the newborn child contains five times more iron than that of its mother, and this store is apparently accumulated in the last three months of its intra-uterine existence—a point to be linked up with the observation that the loss of red cells and haemoglobin is greatest at this period of pregnancy.

Still another factor has come to be recognized during observations upon pregnant women—namely, the influence of functional disturbances of the gastric secretions. Nearly thirty years ago Faber of Copenhagen showed that the proportion of total and of free hydrochloric acid in the stomach has a direct bearing upon the absorption of iron from the food. The proportion of acid in the stomach varies considerably in different individuals, but Strauss and Castle found that the great majority of the women they studied during pregnancy had a marked deficiency.

Here, then, we have abundant evidence that in pregnancy the haemopoietic system is labouring under a strain. In the healthy woman on an adequate diet it can adapt itself to the conditions of strain without either serious symptoms occurring or lasting damage being wrought. But if the woman be already suffering from anaemia when pregnancy occurs, or if her diet be inadequate in the essential constituents we have again a condition of what I may call a clinical experiment superimposed by the occurrence of pregnancy.

Thus the physiological hydraemia of pregnancy, combined with dietetic deficiency and possibly some slight hypochlorhydria, may adequately account for the common but mild anaemia of the hypochromic microcytic type. Obviously there may be also other factors at work, such as unhygienic surroundings, and toxic conditions such as chronic nephritis, pre-eclamptic toxæmia, or pyelitis, as well as actual blood loss from obstetrical complications.

Occasionally we meet more severe anaemias of the same type—women with red counts of  $3\frac{1}{2}$  millions or less and haemoglobin below 45 per cent—which are essentially due to the same factors. But Fullerton of Aberdeen, who has studied the subject carefully, believes that in these cases the women were suffering from a definite anaemia before the pregnancy ensued. Both these forms are susceptible to treatment by large doses of iron with hydrochloric acid, fortified if necessary by a proper diet and hygienic surroundings.

The severe hyperchromic macrocytic anaemia of pregnancy is relatively rare in this country, although so common in India as to constitute one of the major dangers of reproduction. Both the clinical picture and the blood picture resemble Addisonian pernicious anaemia. The most important point of difference is that the disease clears up when the pregnancy ends and does not tend to recur (in the absence of another pregnancy), whereas true Addisonian pernicious anaemia of course has that tendency. Strauss and Castle have shown it to be due to much the same mechanism as true pernicious anaemia. It will be recalled that this involves an essential reaction between an intrinsic stomach factor present in normal gastric juice and an extrinsic dietary factor associated with vitamin B. In their cases Strauss and Castle found that in pregnancy the breakdown was due to the temporary absence of the intrinsic stomach factor combined with an iron deficiency resulting from foetal demands or dietetic errors, or both. Iron, liver extracts, and occasionally transfusion of blood are the lines of treatment, and not infrequently the pregnancy has to be interrupted.

Here again we have an example of the interaction of the physiological strain of pregnancy and the processes of disease. Here also, I submit, is a field for co-operation between physician and obstetrician.

### Polyneuritis

This modern conception of certain anaemias as deficiency diseases naturally led my thoughts to another sometimes associated with pregnancy—namely polyneuritis, in regard to which a similar aetiological claim has been put forward. This is generally regarded as a rare condition, but it is probable that it sometimes escapes diagnosis and that its rarity is more apparent than actual. Most often it occurs in a woman who has been suffering for a considerable number of weeks from hyperemesis gravidarum, so that it usually makes its appearance about the fourth or fifth month of pregnancy. The early symptoms are vague and mainly subjective—extreme weakness and hyperæsthesia of the skin—and there is only too much reason to believe that these have occasionally been looked upon as merely further hysterical manifestations in a woman thought to have been suffering from so-called neurotic vomiting. When actual paresis of the muscles appears and tendon reflexes disappear the condition becomes much more recognizable. Still later there ensues a state of mental confusion and obfuscation, of the type found in association with alcoholic neuritis (Korsakoff's syndrome) and characterized by loss of a sense of place and time and of recent memory. Regarded as a rare form of pregnancy toxæmia and treated as such even to the point of therapeutic abortion, polyneuritis in pregnancy has proved a very fatal condition. Plass and Mengert collected twenty-eight cases from the literature, with a mortality of no less than 68 per cent. My own experience is very limited, but I can recall four cases which corresponded to the description given, although an accurate diagnosis was made in only one. One of these patients died during an induced delivery, and the others very slowly recovered after the artificial termination of pregnancy.

Theobald first drew attention to the striking similarity between this disease in pregnancy and the endemic form of polyneuritis known as beriberi. It is stated that the pathological degenerative changes in the nervous system are identical in the two conditions. Beriberi is accepted as being due to a deficiency of vitamin B<sub>1</sub>, which is now accordingly spoken of as the antineuritic factor.

Now experiments on animals show that during pregnancy there is a transference of vitamin B from the mother's tissues to the foetus as well as to the mammary glands for the functions of which it is essential. In a healthy woman on an adequate diet this drainage of vitamin B can be compensated without the appearance of deficiency symptoms. But if the woman is vomiting severely a vitamin B starvation is caused along with starvation in respect of all other elements of diet and in some cases a polyneuritis may apparently result. On the other hand dietary deficiency alone may cause it in pregnancy for the condition is much commoner in those parts of the world in which beriberi is endemic—that is in which a large proportion of the population exist on a diet deficient in vitamin B. In these latter cases the superimposition of what I have called the experimental conditions of pregnancy with its increased demand for vitamin B may thus reveal for the first time a pre-existing but hitherto occult deficiency in the mother's tissues. Lastly some evidence is slowly accumulating of the good results of prompt treatment of the condition by a diet rich in vitamin B or by concentrated extracts of the vitamin.

Such is the argument. Whether we can as yet adopt this new view in its entirety may be open to debate. What is not in doubt as it seems to me is that it offers a small but most interesting field for co-operative research by neurologists and obstetricians and teaches us when we are treating prolonged cases of hyperemesis to keep a watchful eye upon the nervous system and to see to it that an adequate supply of vitamin B is provided in such diet as the patient is able to assimilate.

### Diabetes

Diabetes mellitus is another disease sometimes associated with pregnancy in which the interaction of the physiological and the pathological conditions provides an interesting study. It is I think undoubtedly true to say that the discovery of insulin and the increasing understanding of the whole subject of carbohydrate metabolism which has followed it have robbed the association of pregnancy with diabetes of its former terrors. But that does not mean that the association is no longer fraught with considerable risk to the mother and even more to the foetus. For one thing the treatment of diabetic women with insulin is making the association much more frequent than before. In pre-insulin days it was definitely rare because the diabetes brought about a depression of ovarian activity and an atrophic condition of the whole genital tract which militated against the occurrence of conception. Nowadays if, under insulin the diabetic woman can be kept in approximately normal health her whole endocrine system apart from the pancreas may function as in a normal woman and there is nothing to prevent conception. The evidence of diabetic clinics is clear on this point.

The occurrence of conception in a diabetic woman is however another example of physiological conditions of extra strain being superimposed upon a disease. If we consider the influence of pregnancy upon the carbohydrate metabolism of the healthy woman we find evidence of strain or at least of a disturbance of the normal conditions. Apart from the accepted increase in the basal metabolic rate which is probably linked up with increased endocrine activity the most obvious example of this is the frequency with which sugar appears in the urine during pregnancy. For this as you are aware there are several possible explanations. The sugar may be lactose about which I would only say that while

lactosuria is common enough in the puerperium it is not in our experience very common in pregnancy. Moreover the recognition of lactose by the appropriate tests does not by any means exclude and may even mask a more significant glycosuria unless tests are applied for glucose also.

In the second place the glycosuria may be of the so-called alimentary type or as Skipper prefers to call it the impaired carbohydrate tolerance or pregnancy. This is due to the liver being less able than usual to synthesize and retain glycogen so that the ingested or any considerable quantity of carbohydrate is followed by hyperglycaemia and glycosuria. So common is this condition found in the first three months of pregnancy that it was propounded as a diagnostic test for early pregnancy by Frank and Nothman and the so-called adrenaline and phloridzin tests are essentially just modifications of it. But none of these tests has the degree of specificity and uniform accuracy necessary for that particular purpose. While not of itself serious alimentary glycosuria is important because it is almost impossible to differentiate it from a mild but true diabetes during pregnancy. After delivery the glycosuria of true diabetes persists the other disappears.

In the third place glycosuria in pregnancy may be and probably most commonly is due merely to a lowering of the renal threshold for sugar. The cause of this increased permeability of the kidney is not understood but it is legitimate to speculate that it is connected with the activity of the anterior pituitary lobe.

There is still another apparently physiological point to be considered—namely the frequency with which acetonuria occurs in pregnancy. Lambie in his masterly review of the subject states that acetonuria occurs in more than 30 per cent of normal pregnancies. It indicates of course that there is a disturbance in the normal proportion of fats and sugars undergoing simultaneous combustion in the body and a significant rise in the ratio of ketogenic to anti-ketogenic substances. Lambie attributes the acetonuria in part to the lowered carbohydrate tolerance which we have discussed and in part to the demands of the foetus for carbohydrate. But whatever be the exact explanation of the phenomenon there is no question that it complicates in some measure the ease of estimating the significance of a glycosuria just as it increases the difficulty of controlling the condition by diet and seriously increases the risk of coma in actual diabetes.

I need not dwell upon the dangers of pregnancy to the diabetic mother because whereas Matthews Duncan in a famous communication in 1882 painted a very gloomy picture and Whitridge Williams in 1909 collected six cases with a maternal mortality of 27 per cent at or shortly after labour (mostly in coma) and an additional mortality of 23 per cent within two years of the records since 1923 when insulin became available tell quite another story. Thus Skipper collected 113 cases with an immediate maternal mortality of only 9.3 per cent, and in thirty-three cases under his own observation at the London Hospital there was no immediate mortality. In the Royal Maternity Hospital at Edinburgh during the last ten years we have had twenty-one patients with diabetes two of whom have been under our care in two pregnancies each. Of these even one case survived till the hospital before delivery and have not been traced. But among twenty deliveries in eighteen patients there was no maternal mortality although it has been impossible to follow the patients up and find out the ultimate results.

While, therefore, the outlook for the diabetic mother has enormously improved, there has been no corresponding improvement regarding the influence of diabetes upon the pregnancy, for the foetal mortality still remains tragically high. Abortion is very common in diabetics, and intra-uterine death in the later weeks adds to the toll, while not infrequently its undue size causes the death during delivery of many a foetus which has survived until term, and yet others die shortly after birth. In Williams's pre-insulin series of cases the foetal mortality, including abortions, was 41 per cent. In 136 pregnancies collected by Skipper the foetal mortality was 45 per cent, and in the thirty-seven pregnancies which he himself observed it was 40.5 per cent. In our twenty pregnancies in the Royal Maternity Hospital in Edinburgh the foetal mortality was 35 per cent.

Priscilla White, writing from Joslin's special clinic in Boston, gives an interesting series of figures. In cases in the pre-insulin era the stillbirth and abortion rate was 44 per cent. After the introduction of insulin there was a reduction in the foetal mortality to 34 per cent, while in cases under the direct and careful observation of the clinic it amounted only to 23 per cent. "Stillbirths and the macerated foetus of the giant type," she writes, "are nearly as characteristic of diabetic pregnancies which are allowed to come to term as they were in the pre-insulin era." Her solution of the problem is the delivery by Caesarean section of "the fully developed but chronologically premature infant." Whether we agree with that view or not, her figures, and those others that I have quoted, are an eloquent plea for the careful ante-natal supervision of such patients by a physician well versed in the management of diabetes, and a clear proof that all such cases must be treated on strictly individual lines and not by any mere routine. For treatment to be fully successful it seems to me that co-operation between the obstetrician and the physician is a *sine qua non*.

### Conclusion

I have chosen these three or four diseases to illustrate my thesis that their association with pregnancy can be understood only in the light of the physiological strain of pregnancy. Other examples might equally well have been chosen. I was tempted, for instance to refer to the temporary benefit in phthisis brought about by the physiological ascent of the diaphragm, compressing the lung and closing up cavities, and to the disastrous relapses which follow the abrupt and ruthless removal of this factor when the uterine tumour suddenly subsides after labour. I was tempted also to refer to kidney diseases, in which the physiological strain is so subtle and so uniform that, as Gibberd has succinctly expressed it, "pregnancy is the best test of kidney function." But these are large subjects, and to have indulged myself would have been to put a wholly unwarrantable tax upon the kindly patience with which you have listened to me.

If I have succeeded in interesting you in my main thesis you will find additional interest in working out its application in these and in other conditions at your leisure.

---

The London hospitals have received during the past year a present of over 5,000 gramophone records by the courtesy of the B.B.C. and the record manufacturing companies. These records which have been used for broadcast purposes, are delivered to the hospitals free by the Gramophone Company in accordance with a schedule drawn up by King Edward's Hospital Fund for London in collaboration with the B.B.C.

## CALCIUM AND PHOSPHORUS DEFICIENCIES IN A POOR HUMAN DIETARY

BY

WILLIAM E. GAUNT, B.Sc., Ph.D.,  
JAMES T. IRVING, M.A., M.D., Ph.D.,

AND

WILLIAM THOMSON

(From the Rowett Research Institute, Aberdeen)

(WITH SPECIAL PLATE)

Dietary surveys and experiments on the feeding of milk and other supplements to children and adults suggest that the diets of various classes of the population both in this and in other countries may be deficient for the maintenance of health. These observations in groups of human beings have led to experiments in which rats were fed on diets similar to those in common use among people whose nutritional state was being studied. One of the best-known of these experiments is that of McCarrison (1926-7), in which a striking parallelism was shown between the health and physique of rats and the health and physique of different tribes in India whose diets were fed to different groups of rats.

In an experiment of this type Orr, Thomson, and Garry (1935) maintained a large colony of rats for two and a quarter years on a diet which approximated the average diet eaten by a working class community in Scotland as ascertained by dietary survey (Davidson *et al.*, 1933). Another colony received the survey diet with the addition of green food and unlimited milk. Four generations of animals were reared. The rats on the human dietary supplemented with green food and milk were quite normal, and in all respects were equally as healthy as rats kept on the Rowett Institute stock diet (Thomson, 1936). On the other hand, with a similar environment and heredity, the animals fed on the survey diet alone showed a slightly impaired reproductive capacity, a considerably increased death rate, a retarded rate of growth, a lowered haemoglobin content of the blood, and a clinically poorer condition. It was thus shown that the addition of green food and milk converted a deficient human diet into one that was adequate, though Orr and his co-workers were unable to state which factor or factors in this diet were responsible for the benefits obtained.

An analysis of the diet showed that it was very deficient in calcium and phosphorus, and the addition of green food and milk greatly increased the content of these elements. The hypothesis that this deficiency might be a major factor in the difference in health and physique of the two groups of rats was strengthened by the fact that numerous experiments with large animals have demonstrated that calcium and phosphorus lack is a common cause of deficiency disease, retardation of growth, and low viability in young at birth (Osborne and Mendel, 1918, Elliot, Crichton, and Orr, 1922, Elliot and Crichton, 1926). Orr (1930) has reviewed the influence of mineral salts in stock feeding, showing the benefits of adding calcium and phosphorus in various forms to the rations of pigs, cattle, and poultry. Similar deficiencies may occur in human diets. A survey made of 607 diets in Scotland in 1926-7 (Orr and Clark, 1930) showed that as family income fell the diet became poorer in calcium. In 205 of the families the intake was less than 0.3 gramme per head per day. In a feeding experiment with the children of these families it

was found that a considerable increase in growth and a definite improvement in health followed the supplementary feeding of either whole milk or separated milk in quantities of from 3/4 pint for younger children to 1 1/2 pints for older children. As the separated milk without the fat or the fat-soluble vitamins contained in the fat had practically the same result as the whole milk it was thought that the great increase in the calcium and phosphorus intake due to the milk might be an important and possibly the most important factor in producing the improvement in growth and health and that the remarkable results obtained earlier by Corry Mann (1926) in children from the increased consumption of milk might be due largely to the same factors.

In view of the obvious importance of calcium and phosphorus it was decided that these elements should be the first to be tested in the experiments now being developed at the Rowett Research Institute in the investigation of specific dietary deficiencies.

### The Experiments

**The Diets**—Three groups of rats were fed on different diets. Group 1 was given the survey diet described by Orr *et al* (Diet 1) whilst Group 2 received the survey diet in which were incorporated the same amounts of milk and green food as were used in the earlier experiment (Diet 2). Diet 3 fed to Group 3 rats was constructed by the addition of salts of calcium and phosphorus to Diet 1 in such amounts that its calcium and phosphorus contents were the same as those of Diet 2.

Analyses for calcium and phosphorus were carried out daily for a fortnight on samples of Diets 1 and 2 excluding the Sundav diets which for each group consisted of bread and water only. Average figures for the whole series of analyses are given in Table I.

TABLE I—Analysis of Diets 1 and 2 (Averages for Twelve Samples of Each Diet)

	Ca	P	Ca P
Diet 1	0.121	0.249	0.030
Diet 2	0.284	0.333	0.34
Difference	0.163	0.089	

Diet 3 was constructed by adding the following amounts of salts to Diet 1 per 100 grammes wet weight: calcium lactate (B.P.) 0.324 gramme, Na HPO<sub>4</sub> (analytical reagent) 0.105 gramme.

The accuracy of this addition and the efficacy of mixing the added salts with the rest of the diet were checked by the analysis of samples of Diets 1 and 3 taken on the same day. The results are given in Table II; the figures for the recovery of the added calcium and phosphorus being in good agreement with the amounts actually added.

TABLE II—Analysis of Diets 1 and 3

	Ca	P
Diet 1	0.099	0.253
Diet 3	0.213	0.340
Difference	0.119	0.087

**The animals used** were Lister Institute hooded rats bred at the Rowett Institute for several generations before the start of the experiment. They were bred from stock the experiment beginning at weaning. Three groups of 21 day old rats, each containing twenty four males and

twenty four females were used. In each group twelve males and twelve females were kept for breeding and four males and four females were killed for examination at 70 and at 100 days of age. In almost every case each male rat in Group 1 had a female litter mate in the same group; in addition these two rats had a male and a female litter mate in both Groups 2 and 3. It was thus possible to compare litter mates of the same age and both sexes in different groups.

**The management of the animals** was suffered like that described by Orr *et al* to merit but little discussion. The amount of food fed was regulated so that a fixed quantity was left every day but the actual food consumption was not measured. Tap-water was given *ad libitum*. The rats were weighed at the beginning of the experiment and thereafter twice weekly. The animals killed for examination were radiographed prior to dissection of the upper and lower incisors and the remaining tibiae and fibulae of both legs. The upper incisors and the tibiae of the right leg were used for histological examination while the lower incisors and the tibiae of the left leg were reserved for chemical analysis. The remaining rats of each group were used for breeding standard methods being employed.

The experiment is being carried out over three generations; the results reported in this paper dealing almost entirely with the first generation. Data relating to all the generations will be published in full at a later date.

### Results

(a) **The Rate of Growth**—The accompanying chart shows the rate of growth of the male rats in the first generation. It will be seen that the growth rates of

Chart showing the average growth of male rats from 21 to 110 days of age.

Groups 2 and 3 are identical and are much slower than that of Group 1. Exact similar results were obtained with the females though as is always the case the weights were lower than those of the males. The growth curves of the second generation have also been obtained and it has been found that in this case the Group 1 rats do not grow as fast as those in Group 2, but are

much better than those in Group 1. The general condition of the rats on Diet 1 was poor, these rats had not the sleek appearance of their litter mates in Groups 2 and 3, who were always in good condition.

(b) *X-Ray Photographs*—In all cases the films showed a striking difference in the degree of calcification of the rats in Groups 1 and 2, very little difference could be seen between Groups 2 and 3. Figs 1, 2, and 3 (Special Plate), reproducing x-ray photographs of litter mates in the three groups, demonstrate this fact.

(c) *Histological Examination of the Teeth*—This examination was used to demonstrate the relative values of the three diets, in the same way as was done by Mullick and Irving (1937) in assaying the nutritional value of Indian diets. Schour and his co-worker (Schour and Ham, 1934) and many others have pointed out that the width of predentin in the rodent incisor tooth offers a very delicate test for the degree of calcification, being wider when calcification is impaired. Longitudinal sections of decalcified upper incisor teeth were cut, stained with haematoxylin and eosin, and the predentin width in the apical part of the tooth measured. The normal value for this width is from 16 to 20  $\mu$ . The average results obtained from the first generation are given in Table III.

TABLE III—Width of Predentin ( $\mu$ ) in Longitudinal Section in Upper Incisors (Average Results from the First Generation)

Age in Days	Sex	Groups		
		1	2	3
40	M	29	25	22
	F	31	20	21
70	M	41	23	19
	F	34	22	19
100	M	38	20	21
	F	25	20	21

These results show quite clearly that calcification is deficient in the rats of Group 1 but is normal in those of Groups 2 and 3. In addition it is possible that calcification is most impaired in Group 1 at 70 days, improving after this time. Photomicrographs of teeth from litter mates are reproduced in Figs 4, 5, and 6. The section of the tooth from the Group 1 rat shows vascular inclusions in the predentin, these were quite commonly found in teeth from Group 1 rats at 70 and 100 days of age, but were always absent in the teeth of rats in the other two groups. The histological examination of the bones failed to reveal any differences which could be compared quantitatively. Results from this examination have not been included in this paper.

(d) *Chemical Analyses*—These are limited to the ash contents of the femur, tibia, and fibula combined, and of the lower incisors. The results are given in Table IV. The percentage of ash in the bones of Group 1 rats is in every case much lower than the corresponding figures for the animals in Groups 2 and 3. The differences between Groups 2 and 3 are not significant. The lowered calcification of the bones of Group 1 rats and the similarity in the calcification of Group 2 and Group 3 animals are more truly expressed when the ash contents (in absolute amounts) of the bones of Groups 2 and 3 are stated as percentages of those of the Group 1 rats. Despite this similarity it cannot, however, be concluded that calcium and phosphorus in inorganic form are equally as available as those elements in milk and green food, since there are no figures for the total calcium and phosphorus contents of the animals. The relative availability can only be decided by balance experiments.

TABLE IV—Weight and Composition of Dry Extracted Bones and Teeth (Average of Four Rats)

		2	0.4653	0.2895	202	61.88	0.1308	0.1025	130	78.63
		3	0.4897	0.3075	213	62.75	0.1302	0.1020	129	78.65

The tooth-ash figures show much slighter differences between the three groups. This result is in marked contrast to the histological findings, which follow the bone ash figures closely. This lack of correspondence between the histological and chemical data with teeth has often been noted by us and by other workers, and shows that the histological examination is a much more sensitive test of normal tooth calcification than is chemical analysis.

(e) *The Reproductive Performance of the Rats of the First Generation*—This is shown in Table V.

The figures show that the rats from Group 1 mated less readily, producing smaller litters with a low weaning weight, the reproductive performances of rats from Groups 2 and 3 were considerably better.

TABLE V—Reproductive Performance of First Generation Rats

	Group		
	1	2	3
Average time between introduction of milk and birth of litter (days)	48	34	26
Average number born per litter	8.7	9.7	10.0
Average weight at birth (grammes)	5.30	5.36	5.48
Average weight at weaning (21 days) (grammes)	24.3	32.0	27.3

### Discussion

The results quoted show clearly that, using rats bred from stock, the improvement in a poor human diet induced by milk and green food supplements can be largely reproduced by the addition of equivalent amounts of calcium and phosphorus salts. This result is in agreement with the work of Sherman and Campbell (1935), who found that the improvement in the nutritional quality of a diet caused by adding dried milk was also obtained by using an equivalent amount of  $\text{CaCO}_3$ . In a recent paper Coward *et al* (1938) have shown that the addition of calcium and phosphorus salts to a poor human diet fed to rats increased the ash content of the bones. These results are of great interest in confirming our findings, but it is unfortunate that the diets chosen do not approximate

more closely to those actually consumed by man as shown by dietary surveys. Further we cannot agree for the reasons given above that these authors are justified in stating that the calcium in milk is no more available to the animal than is the calcium in inorganic salts. This can only be decided by balance experiments and indeed the literature on this subject states quite clearly that milk calcium is the more readily available (Givens and Mendel 1917 McCluskey and Mendel 1918).

### Conclusions

It has previously been shown that the nutritional value of a poor human dietary can be greatly improved by the addition of milk and green food supplements. The experiments here reported demonstrate that in rats bred from stock this improvement is due largely to the calcium and phosphorus contained in the supplements. This conclusion is of particular interest at the present time when much stress is being laid on mineral metabolism and it is being realized that a deficiency of calcium in particular is likely to occur in human diets. An increased consumption of milk as now widely practised in America is the most efficient means of ensuring an adequacy in this respect.

We wish to express our indebtedness to Sir John Orr FRS for his interest and criticism.

L Lofgren (*Finska LakSallsk Handl* December 1937 p 937) has searched for a patent foramen ovale among the 785 bodies examined post mortem at the Medico Legal Institute in Helsingfors during 1935 1936 and 1937. No child under 10 was included in this study and there were only 170 women. In as many as 120 cases (15.3 per cent) a patent foramen ovale was found. The smallest only just admitted a fine sound the largest was over 1 cm in diameter. In most cases the diameter was from 2 to 5 mm. Comparing his findings with those of other observers the author notes how widely they have differed partly no doubt because of the differences in the ages of the persons examined. Those—and they are in the majority—who have included children of all ages in their studies must necessarily find a comparatively high proportion of cases for the anatomical closure of a patent foramen ovale may occur long after birth. A patent foramen does not seem to influence growth for the average height of the adults examined by the author was normal and he is of the opinion that a patent foramen gives rise to no anatomical changes such as hypertrophy or dilatation of the heart. With regard to the diagnosis during life he considers this impossible as the condition so seldom gives rise to clinical manifestations when unaccompanied by other heart lesions. The author discusses briefly the association of a patent foramen with paradoxical or crossed embolism.

## FRACTURE OF THE NECK OF THE FEMUR

BY

H A BRITTAIN, M Ch, F R C S

Orthopaedic Surgeon Norfolk and Norwich Hospital

(WITH SPECIAL PLATE)

The treatment of fractures of the neck of the femur by the insertion of the Smith Petersen nail is now so firmly established that attention is focused more on refinement of the technique of insertion than on comparison with other methods. As Hey Groves has said the Smith Petersen nail has completely dominated the situation. There are certainly several other fractures which have more pressing claims to Kellogg Speed's title of the unsolved fracture.

### A Simplification of the Smith Petersen Method

A year ago I published an account of a method of inserting the nail. I was not claimed that this was exactly original but I suggested that it was probably the most simple procedure yet recorded. I have since further simplified this considerably and I now feel that an one with a moderate degree of operating skill—equivalent to that possessed by any competent house surgeon—can place a Smith Petersen nail correctly at the first attempt by a method which has the additional advantage that it demands a minimum of teamwork and in the end it does not take long. The average duration of the operation in each of the last dozen cases has been slightly more than half an hour and this comprises the total time spent by the patient in the theatre.

### TECHNIQUE

The first step is to attach the patient's feet to the foot pieces of an orthopaedic table by plaster of Paris. Reduction is performed by the Whitman manoeuvre, other variations such as those of Tavernier Leadbetter etc. are reserved for difficult fractures. Traction is exerted by hand only; it is difficult to assess the amount of traction when using a screw axis is used. When the necessary traction is obtained by hand it is secured by one arm of a traction skin having been protected with sterile oiled towelling. The nail is applied to the skin over the fracture. The nail is placed over the middle point of the line joining the symphysis pubis and anterior superior iliac spine. The nail is situated half an inch medial to the anterior superior iliac spine and the opposite anterior superior iliac spine. The nail is placed anterior to the lateral margin of the great trochanter, approximately one and a half inches from its upper margin. The fourth is put in position midway between the first and third. A calibrated guide is then introduced directly anterior to the neck of the femur along the line of these clips until it abuts against either the head of the femur or the lesser trochanter. A fifth Michel clip is applied one and a half inches posterior to the point of entry of the guide.

Antero-posterior and lateral radiograms are now taken (Figs 1 and 2). The antero-posterior direction is selected from either the position of the guide or that of the clip and the lateral direction from the position of the guide. The point of entry of the guide in the bone is determined by a Michel clip point somewhere between the guide and the fifth 1 1/2 inch clip. In the last twenty cases more than 70 per cent of the nail was parallel to the guide or deviating only slightly from it. The calibrations of the guide are counted and the nail is driven to allow for the fact that the guide is in front of the neck and therefore nearer the fracture it must also be driven to allow for impaction. A full inch of nail is now driven between the point of entry of the guide and the point of the Michel clip. The cortical bone is drilled with a quarter inch

drill. A quarter inch drill is essential as by this means the direction of the guide is not interfered with by pressure on the cortical bone.

At this stage a non-calibrated guide is introduced in the direction chosen. I have discarded the use of the calibrated guide in the bone, because of the risk of impaction of the nail on a calibration. It has been suggested that the guide may bend at the site of the fracture but this will not occur if the feet have been fixed in plaster of Paris. The Smith-Petersen nail is gently tapped home, it can be decided when the head is flush with the bone by using the calibrated guide. The wound is then closed with one suture.

*Table of Results*

Patients	Died	Non union	Arthritis
66	7 (one after union)	4	1

Percentage of all patients with bony union 85.70  
arthritis (excluding deaths) 5.68

### Time of Operation

The optimum time of operation I consider to be, as a rule, on the third day after the fracture. The patient has by then got over the initial shock, and should not yet have developed bed-sores, pneumonia, delirium tremens, etc. Pneumonia and passive congestion are indications for immediate operation. It is here that the use of the nail becomes a life-saving procedure. The elderly patient with pneumonia has a poor chance of survival if she is immobilized by an untreated fracture of plaster-of-Paris. I have been impressed by the great improvement which takes place in these patients after they have been rendered mobile in bed by the insertion of a nail. Three of the five deaths have been due to pulmonary embolus. I think it is significant that in all those cases operation was postponed, being performed between two and three weeks after the fracture. The other two deaths were due to cerebral haemorrhage and pyonephrosis, the latter unconnected with the insertion of the nail.

### Lateral and Trochanteric Fractures

I have repeatedly been disappointed at the tendency to late adduction in these fractures when treated by immobilization in plaster or by the Roger Anderson well-leg traction. Adduction has taken place in some patients after five months immobilization, even before weight-bearing had commenced, and when on the clinical and radiological evidence, the fracture had seemed firm. Even at the best, with immobilization, one has the handicap of stiff knees to contend with, and, at the worst, adduction or external rotation deformity in addition. I therefore attempt to nail all these fractures. It may be necessary to start the nail very low on the shaft to get good bone but this is nearly always possible. The nail need not extend right into the head of the femur. The cortical bone of the superior border of the neck affords a sufficient hold, and accidental penetration of this until union takes place is not a very serious disadvantage. I consider that an attempt to surmount the technical difficulties of the operation is well worth while. The benefit to the patient from immediate mobility leaves me with the impression that nailing is the treatment of choice.

### Reduction

Reduction is usually obtained by the Whitman procedure, and it is rarely found necessary to vary this. Before the patient is placed on the orthopaedic table the hip is always flexed to disimpact the fragments. I have used the Leadbetter method of reduction, but consider its weak point is that the fractured limb is held by an

assistant. If a ray control is to be reliable certain factors are essential: (1) there must be no movement of the fractured limb, (2) the tube must be constantly centred over the same point. I was recently privileged to watch the insertion of a Smith-Petersen nail during which the limb was held by an assistant instead of being secured on a table. Comparison of two antero-posterior skiagrams revealed a marked discrepancy in the position of the nail, the second one showing it to be dangerously near the cortical bone of the head.

### Impaction

I agree with Watson Jones that gross impaction is unnecessary if reduction is accurate. If there is a gap between the fragments which cannot be reduced by manipulation I impact by a dozen gentle blows with the Stirling or Smith-Petersen punch. I reserve impaction for those cases in which reduction has not been perfect and a gap is left, and also in the very aged where the nail has traversed the head too easily, like a knife through butter.

### After-treatment

The usual routine is to keep the patient in bed for four weeks. No precautions other than this are necessary with a well-placed nail. At the end of four weeks an x-ray photograph is taken and if the nail is still in good position, possibly with signs of early union present, the patient may be allowed to sit up out of bed. At the end of eight weeks progression on crutches is permitted, but no weight-bearing until the end of three months or until bony union has occurred.

### Complications

Complications are due to (a) changes in position of the nail, (b) arthritis.

#### (a) CHANGES IN POSITION OF THE NAIL

Of sixty-six, seven have broken out, two coming out in their longitudinal axis after union. I have found that nails emerge in three ways: (1) in the longitudinal axis of the nail, (2) by an external rotation strain, and (3) by an adduction strain.

1 *In the Longitudinal Axis*—It may be only coincidence, but I have had only one nail come out in its longitudinal axis since I have been using nails with snagged edges, whereas previously this was quite common. Whether callus forms between the teeth it is difficult to say, as against this one knows that eventually rarefaction occurs all round the nail. This resulted in one case of non-union in the last twenty-five patients. This patient was discharged as an in-patient at eight weeks, and unfortunately did not attend again for over six months. He was then found to have non-union, and the nail had withdrawn a distance of one inch. I performed a bifurcation osteotomy for non-union on the lines laid down by McMurray.

2 *External Rotation*—I consider this is the commonest method of breaking out. It is the position taken by the fractured limb, and puts most strain on the fracture and nail. Internal rotation is a definite active movement, and though more forceful than external rotation is not a rule adopted by the patient. It can be guarded against by applying a plaster-of-Paris T-piece to the foot or the leg.

3 *Adduction Strain*—This occurs when a nail is placed in too perpendicular a position. If the arc described by the point of the nail can clear the lip of the acetabulum when the limb is adducted slightly, I consider the nail is in danger of breaking out by this strain. If so well placed that it will be protected by the lip of the acetabulum I

consider it to be safe. That holds also for external rotation strains but it is difficult to determine this in a lateral photograph. The best placed nail is that which is directly central. Any deviation from this however should be towards a posterior or low position. When a nail has broken out I always replace it immediately after the diagnosis has been made and with the exception mentioned above union has always occurred.

#### (b) ARTHRITIS

My experience of the closed treatment of fracture of the neck of the femur—namely the Whitman procedure—is not extensive enough for me to compare the incidence of arthritis with that method and the incidence with treatment by the Smith-Petersen nail. In my cases of SIXTY SIX closed nailings there were three cases of arthritis. To these I might add twelve previous cases of open nailings, nine of these patients I have communicated with and apart from two pseudarthroses they have not developed arthritis. I feel that the nail should not be blamed and that the truth of the matter is that we are now seeing over 80 per cent of bony unions and a much higher survival rate and in consequence more arthritis. The arthritis is of a degenerative type sometimes called aseptic necrosis of the head of the femur. Contributory causes to its occurrence are (1) delayed union (2) in accurate reduction and in consequence faulty weight-bearing (3) excessive impaction (4) perforation of the cartilage by the guide or nail (5) pre-existing arthritis.

Eric Lloyd has stated that the abduction fracture should not be nailed. Figs 4 and 5 (Special Plate) show arthritis following six years after an abduction fracture with slight displacement. Whether this was due to the fracture not being reduced or to degenerative arthritis as a result of inadequate blood supply it is difficult to say but I hold most emphatically that any fracture abduction or other wise should be reduced and nailed if there is any displacement.

#### Summary

- 1 The treatment of fractures of the neck of the femur by the Smith-Petersen nail has been generally adopted.
- 2 A method of insertion of the Smith-Petersen nail is described.
- 3 It is suggested that this is the most simple method yet described, necessitating no elaborate instrumentarium and that by its use the nail can be placed correctly in about half an hour.
- 4 Complications are due to breaking out of the nail or to arthritis.

In August 1937 the signing of the National Cancer Institute Act authorized the establishment of such an Institute as part of the US Public Health Service. For the necessary building and equipment 750,000 dollars were allotted and a yearly appropriation of 700,000 dollars is needed to maintain the Institute. The primary object of this Institute is to be research into all phases of cancer—diagnosis prevention and treatment. Knowledge gained in the Institute will be available to medical men and agencies all over the world. The appropriation also makes it possible for funds to be utilized as grants in aid for research. The Institute is given the power to establish and maintain research fellowships with such allowances as the Surgeon General may consider necessary. In September 1937 a National Advisory Cancer Council was formed under the Chairmanship of Surgeon General Thomas Parran consisting of Dr James Ewing, Dr Francis Carter Wood, Mr C. C. Little, Sc.D., Mr Arthur H. Compton, Ph.D., Mr James B. Conant, LL.D. and Dr Ludwig Hektoen.

## MALIGNANT TUMOUR OF THE THYMUS GLAND

BY

R. G. PROSSER EVANS, M.R.C.S.

*Lieut. Senior House Physician, Brompton Hospital, S.W. 19  
Acting Tuberculosis Physician (Sydney) Welsh  
National Memorial Association*

(WITH SPECIAL PLATE)

Tumours of the thymus gland are comparatively rare and therefore the following case appears to have a definite interest.

#### History of the Case

A male child 5 years old was first taken to the family doctor on April 12 1937 because he had complained of a tight chest during the previous two weeks. He had had measles in February 1937 followed by a normal convalescence. His health had been good and he had always been an active child. Both parents and one brother were alive and well and there was no history of tuberculosis in the family.

The patient was seen in consultation on April 15 1937. He was born a blue baby and the parents were told at the time that there was something wrong with his heart. A slight dry cough was present but no expectoration. The appetite was poor and there had been much recent loss of weight. Shortness of breath and tightness of the chest were the most pronounced features.

On clinical examination the patient was obviously distressed and there was marked cyanosis of the lips and face. He was able to stand but could not walk a step owing to respiratory embarrassment. He was fairly well nourished although he had obviously lost weight recently. The temperature was 99° F and the pulse rate 120 per minute. There was no clubbing of the fingers. Nothing definite was noted in the mouth or nasopharynx but the superficial veins over the upper abdomen and chest were very prominent. On the right side of the neck in the region of the right lobe of the thyroid gland was a fluctuating swelling that appeared to transmit an expansile impulse on coughing. The heart apex beat was displaced to the left. The right chest was immobile and showed a decided dullness. There was absolute dullness on percussion and the breath sounds were tubular in character. The heart sounds were accentuated but no definite valvular lesion was present. No abnormal physical signs were observed in the left lung apart from very harsh breath sounds. The liver dullness appeared to be increased but nothing definite was palpated in the abdomen. Both testicles were present in the scrotum. A ray examination of the chest showed a dense opacity occupying the inner parts of all zones of the right lung bed and shading off towards the periphery. The diaphragm outline and costo-phrenic sulcus were obliterated. The heart and mediastinum were displaced to the left. The radiographic appearances suggested a large pleural effusion. After consideration of the clinical and radiological aspects of the case a diagnosis of mediastinal neoplasm was made.

The patient was admitted to hospital for further examination. His temperature now varied from 99° to 100° F the pulse rate from 120 to 140 and the respiration rate from 30 to 40 per minute. The following investigations were carried out by Dr A. F. Sladden, pathologist to the Sydney General Hospital.

**April 20 Pleural Fluid**—The fluid was turbid and of a brownish colour with clot. Microscopical examination revealed a few polymorphous lymphocytes plus a few endothelial cells. No tubercle bacilli or other organisms were seen and culture was sterile. Erythrocytes plus pH 6.9 protein 3 grammes per cent. albumin-globulin ratio 2:1.

**April 21 Blood Count**—Red cells 4,600,000 white cells 15,200 per cmm. haemoglobin 90 per cent colour index 1.0. Average diameter of red cells 7.1.

**April 2 Pleural Fluid**—The fluid contained a large amount of blood. Films showed blood cells, polymorphs, and lympho-

cytes No tubercle bacilli or other organisms present, culture was sterile

*April 28 Blood Count*—Red cells 3,742,000 white cells 41,000 per cmm haemoglobin 64 per cent colour index 0.82 Polymorphs, 81.0 per cent, lymphocytes, 11.5 per cent, monocytes, 6.5 per cent, eosinophils, 1.0 per cent, basophils, 0.07 per cent, anisocytosis ±

Further x-ray examinations were made on April 17, 22, and 29. These radiographs showed some slight increased translucency in the upper zone of the right lung with what appeared to be a definite lateral border to a mediastinal mass. The child's condition gradually deteriorated. His weight decreased, the dyspnoea became more severe and he was obviously gravely distressed. The physical signs remained unchanged. At the request of his parents he was discharged from hospital on May 7. He died a few hours after his arrival home.

### Post-mortem Findings

The body was very emaciated. There was no oedema of the legs. No enlarged glands were present in the neck. A cystic swelling was seen in the region of the right lobe of the thyroid gland. On opening the thorax the right pleural cavity was filled with a brownish-coloured fluid—about three pints in all. A large growth was situated in the anterior mediastinum. No glands were palpated in the abdomen. The thoracic contents were removed *en bloc*. I am indebted to Dr W. H. Tytler, research bacteriologist to the Welsh National Memorial Association, for the following report:

'A large soft relatively avascular tumour [see Special Plate] measuring 5 by 5 by 4 inches lies in the anterior mediastinum in front of the trachea, and extends from just below the thyroid gland downwards for about 5 inches. The tumour is adherent to the upper part of the anterior parietal pericardium, and extends downwards to the apex of the pericardial sac as a broad tongue of growth about half an inch thick.

"It does not infiltrate or enclose the trachea but the ascending limb and arch of the aorta and great vessels are surrounded and compressed but not infiltrated by it. A thin layer of growth extends downwards, infiltrating part of the posterior wall of the left auricle and ventricle and isolated plaques of soft yellowish-white tumour tissue lie in the anterior wall of the left ventricle and at the apex of the heart, and are covered by the visceral pericardium. The cut surface of the growth presents a smooth, whitish yellow, slightly lobulated appearance.

*Heart* This appears normal apart from infiltration of its walls by the tumour as described. Small flattened thrombi lie in the left ventricle and aortic valve. The pericardium itself is nowhere infiltrated by the growth, and the sac contained no fluid.

*Right Lung* Normal and air-holding.

*Left Lung* This is compressed and practically airless. A few indefinite fibrous like thickenings are felt over the left margin of the upper lobe, and the cut surface shows a purulent bronchitis.

### MICROSCOPICAL SECTIONS

The tumour is composed of a diffuse undifferentiated mass of cells resembling small lymphocytes. The stroma is very scanty and there are practically no reticulum cells. The blood vessels of which there are comparatively few, are small and thin walled.

*Metastases—Heart* The areas involved show a solid mass of tumour cells on the surface and extending into the muscle to about one-half of its depth, forming columns and layers between the muscle cells.

*Left Lung* Sections including the thickened areas described show extensive areas of infiltration by tumour cells which

involve the pleura and form dense masses round some of the blood vessels and bronchioles. There is evidence of a purulent bronchitis, with desquamation of bronchial epithelium and leucocytic infiltration, and the alveoli are largely collapsed.

*Right Lung* Apart from some congestion, sections show nothing noteworthy.

### "INTERPRETATION OF FINDINGS

'The tumour is a malignant lymphoma and on account of its situation possibly arises from the thymus gland. Its origin, however, cannot be stated with any degree of certainty as the thorax contains many other lymphocytic structures from which it may have arisen. The findings indicate that death was due to asphyxia and venous obstruction.'

### Pathology

Much is still unknown about the normal functions of the thymus gland and the part it plays in conditions of disease. The weight of the gland in relation to that of the body is greatest at birth. The maximum actual weight is attained at about the fifteenth year, and thereafter involution occurs—that is, at puberty, and not when the body is fully grown. This suggests an intimate relation between the thymus and the genital glands, and experimental results confirm this view. In tuberculosis the gland is very rarely affected. Small nodules and occasionally small caseous masses may be present in acute miliary tuberculosis, but neighbouring lymphatic glands may be involved by tuberculous infection without lesions occurring in the thymus.

The thymus gland is rarely the seat of either primary or secondary new growths. Voges (1926) notes that tumours of the gland were known to Virchow, who regarded it to be often the starting-point of lymphosarcoma. The commonest growth appears to be a primary malignant tumour composed of small round cells with scanty stroma. Most writers describe it as a round celled sarcoma or lymphosarcoma, but some observers maintain that it is of epithelial origin. The carcinomata of the thymus have been the subject of much controversy, as they present many peculiar characteristics. One form of cancer may be ill defined and resemble sarcoma, while a second variety may take the form of ordinary 'medullary' carcinoma. Other observers classify the carcinomata of the thymus as small-celled and large celled varieties, and also a form of tumour special to this gland, the lympho-epithelioma. In view of the two types of cells present in the thymus—epithelial and lymphoid—this growth may be called a true thymoma, a term which has been rather loosely applied to various forms of growth originating in the gland. Pure epithelial tumours are extremely rare. "Thymic epiblastoma" is a term used by Foot and Harrington (1923) in their description of a case.

Gandy and Piedelievre (1920) describe a tumour resembling a lymphadenomatous growth which infiltrated neighbouring parts, including the heart and superior vena cava. It is interesting to note here that Symmers and Vance (1921) subdivide lymphosarcomata into two varieties: (1) a growth consisting of masses of lymphoid cells separated by strands of connective tissue (the usual lymphosarcoma), and (2) tumours histologically resembling Hodgkin's disease containing giant cells and eosinophil elements.

Bosanquet and Lloyd (1932) found forty three instances of adequate records in the literature on tumours of the thymus gland. They state that twenty nine of these were carcinomata and fourteen sarcomata, ten of the latter being lymphosarcomata. Of the carcinomatous tumours

twelve were apparently lympho-epitheliomata thirteen were described simply as carcinomata and four as epitheliomata. Davidson (1933) quotes the recent view of Barnard that many of the tumours in the mediastinum called lymphosarcomata are in reality a form of carcinoma. The interpretation as to the character of malignant tumours seems to depend on the view held concerning the peculiar histological structure and nature of the small thymus cells and in any case the classification of tumours according to histological structure appears to be unsatisfactory. Hassall's corpuscles may or may not be present but their absence does not negative an origin in the thymus gland.

Metastases occur most frequently in the neighbouring lymphatic glands in the pleura and in the lungs. They may also arise in the abdominal glands liver kidneys suprarenal bodies stomach ovary and very occasionally in the bones.

Simple tumours such as fibroma and myxoma are said to occur in the thymus and also cysts of varying kinds both developmental and dermoid (Ewing 1916).

### Symptomatology

In most cases of tumour of the thymus gland dyspnoea is the predominant symptom usually of increasing intensity and frequently paroxysmal in character. This is accompanied by cyanosis and often oedema of the neck and face due to pressure on the venous trunks and even involvement by the growth. The pericardium and heart muscle may be infiltrated by the growth. Haemoptysis may occur owing to involvement of the bronchial vessels. Pleural effusions are a frequent accompaniment and the fluid is usually haemorrhagic. Pneumothorax has also been met with. The case described shows several of the above features increasing dyspnoea inclined to be paroxysmal in character cyanosis haemorrhagic effusion and pneumothorax. The heart muscle was infiltrated by the growth and deposits were found also in the left lung and pleura. Metastases are often the cause of the most prominent symptoms—for example abdominal symptoms—and secondary deposits occurring in the spine may give rise to a paraplegic condition before the seat of the primary lesion is recognized.

It is more usual for tumours of the thymus gland to occur in childhood. Among the cases which Bosanquet and Lloyd (1932) collected there were eighteen instances of carcinoma in persons over the age of 40 and ten below that age. The sarcomata were more evenly distributed three occurred in the first decade of life two in the second three between 21 and 30 years of age and three between 31 and 40 the remaining two being in persons aged 60. Bedford (1930) describes a carcinomatous growth of the thymus in a newborn child. Death was caused by asphyxia, and metastases were present in the lung liver bones, and skin.

Several authors discuss the association of thymic tumours with other diseases—namely lymphosarcoma associated with lymphatic leukaemia and thymic tumours occurring in patients suffering from myasthenia gravis—most of which are regarded as having been benign in character although originally reported as otherwise by the authors. Two cases have been described in which thymic tumour was present in patients with tuberculosis. Ewing (1916) reports a case in which repeated attacks of tonsillitis occurred. In view of the close resemblance in histological structure between the tonsil and the thymus the association of these symptoms is worthy of note.

### Diagnosis

It is extremely difficult and often impossible to make an absolute diagnosis of thymic tumour during life. In most cases dullness on percussion over the upper part of the sternum dyspnoea venous engorgement and the radiographic appearances will help in arriving at a tentative diagnosis of the condition. Unfortunately one or more of these symptoms and signs are frequently absent and the radiograph may not show the shadow of an enlarged thymus as instanced in our own case. Screening examination shows that the opacity increases in size when the child cries.

The diagnosis from tuberculous enlargement of the superior mediastinal glands rests upon the characteristics noted above. An intradermal Mantoux test would also prove helpful in the differentiation. In our own case the radiological diagnosis of a thymic tumour was rendered difficult by the appearances of a massive effusion in the right pleural cavity although later films showed an apical but defined edge in the upper mediastinal area on the radiograph suggesting the possibility of a mediastinal tumour. Unfortunately the child was so ill that it was deemed inadvisable to prolong the examination for screening and lateral radiographs to be taken.

### Treatment

Apart from symptomatic and palliative measures the treatment of these cases is very unsatisfactory. A case is recorded by Lenz (1928) in which an epithelial tumour of the thymus was successfully removed by operation and the patient recovered. Owing to the involvement of the great vessels in these tumours in the majority of cases it would appear that surgical methods are extremely limited. In our own case surgical removal of the tumour would obviously have been impossible. American workers report success in treating mediastinal lymphoblastomata with deep x rays but although improvement occurs this is probably only transient. The thymus like lymphoid tissue generally is very sensitive to the action of x rays degenerative changes are produced in the lymphocytes which may become destroyed. In early life the thymus has great powers of regeneration as is seen when a part is removed. Davidson (1933) records a case similar to the one here described in a child of 3 years. Urgent dyspnoea was the main symptom and a blood-stained effusion was present. A considerable improvement was brought about for a time following deep x ray therapy but subsequently the patient died ten weeks after admission to hospital. The growth in this case was classed as a sarcoma, and sections showed it to be composed of small round cells of the lymphoid type in a fibrous reticulum.

### Prognosis

In the case reported by Bosanquet and Lloyd (1932) the disease seems to have been present for several years before the patient eventually died. Kneringer and Priessl (1923) describe the case of a man aged 71 in whom the disease had apparently lasted for over eight years. While Miller (1926) records a case in a child of 9 years who died in twenty-six days. In the present case the patient died within thirty-nine days after the onset of symptoms. A duration of two years is not rare but the majority of patients die within a year of the onset of symptoms.

### Summary

1. A case of malignant tumour of the thymus gland has been described. It presented many typical features

from the clinical standpoint, but the radiological appearances were not diagnostic

2 The tumour infiltrated the heart muscle and the left lung and pleura, but the pericardium was free from involvement. The arch of the aorta and great vessels were surrounded by the tumour, but not infiltrated

3 The origin of the tumour cannot be stated with any degree of certainty, but it appears to be a primary growth in the thymus gland itself

4 The microscopical findings show the tumour to be composed of a diffuse undifferentiated mass of cells resembling small lymphocytes. It is not a true "thymoma" in the strictest pathological sense, but more correctly a malignant lymphoma

5 Post-mortem findings indicate that death was due to asphyxia and venous obstruction

## SPONTANEOUS HAEMOPNEUMOTHORAX

By

**JAMES MAXWELL, M D, F R C P**

Assistant Physician St Bartholomew's Hospital Physician,  
 Royal Chest Hospital Consulting Physician Royal  
 National Sanatorium Bournemouth

(WITH SPECIAL PLATE)

Although a spontaneous pneumothorax is by no means an uncommon event, it is comparatively rarely that the condition proves to be serious. In most cases the collapse of the lung results from the rupture of an innocent cyst or bulla into the pleura, and the air is gradually absorbed from the pleural cavity. Occasionally a valvular opening may occur, with the result that there is a mounting pressure in the pleura and serious interference with respiration, at other times, especially when there is active tuberculosis in the lung, there may be pleural effusion or even pyopneumothorax. Severe haemorrhage in cases of spontaneous pneumothorax is rare enough to justify the publication of the notes of the following case

#### Case Record

X Y a man aged 24 had always enjoyed good health. On August 28 1937, he was unscrewing the caps from heavy hydrogen cylinders: this involved considerable strain on the muscles of the chest and arms. He felt no ill effects at the time, but was awakened at 5 o'clock the following morning by a severe pain in the left side of the chest. He got up at his usual time and felt quite well, except that any strain or sudden movement produced a stitch-like feeling in the left side of the chest and some shortness of breath. At that time he felt as if there was some fluid jumping up and down on sudden movement. He was reasonably active during the day, but was short of breath on attempting to play tennis. The following day he became still more short of breath and felt severe and increasing pain in the left side of the chest. He

returned home early and went to bed: the dyspnoea and pain were much relieved by rest. On the same night he felt very faint and his doctor noticed that he appeared to be blanched exactly as if he had had a severe internal haemorrhage. Physical examination of the chest revealed that there were no breath sounds on the left side and a radiograph was taken (Fig 1) which showed a pneumothorax and a considerable quantity of fluid. The patient was seen on September 3, when, in view of his extreme pallor, it was suspected that there had been bleeding into the left pleural cavity. The chest was explored with a needle and blood was found. He was admitted to the St David's Wing of the Royal Northern Hospital and on September 9 34 oz of liquid blood were removed from the left pleura, using a wide bore needle and a rotunda syringe. No difficulty was experienced and the general condition of the patient was good, but it was decided not to attempt to remove more blood at that time because it was impossible to be sure that further bleeding would not take place. The chest was screened on the following day, and it was then seen that a considerable amount of fluid was still present. On September 12 it was decided to empty the chest as far as practicable, and a further 30 oz of blood was removed. The breath sounds were found to have returned over the lower lobe and the percussion note became resonant. The patient was kept in bed for a week and given an iron tonic. His general condition rapidly improved and the chest condition remained satisfactory. He was seen again on September 29, when he appeared to have recovered his health, and an x-ray film (Fig 2) showed complete re-expansion of what appeared to be a normal lung.

#### Discussion

The occurrence of a haemopneumothorax raises several points of importance. In the first place it is almost impossible to imagine it happening in a case of spontaneous pneumothorax unless there had been some previous abnormality in the pleural cavity or some lesion in the underlying lung. In this particular case there was no clinical or radiological evidence of pulmonary tuberculosis, and it seems almost certain that the bleeding must have been caused by the rupture of an adhesion between the two layers of the pleura. It would be possible in this way for a small vein to be opened and for a gradual haemorrhage to result. That the bleeding was gradual is shown by the fact that blanching was not noticed until at least forty-eight hours after the pneumothorax must have occurred.

It is clear that in such cases the blood must be removed as completely as possible from the pleural cavity, but choice of the appropriate time may be difficult. If the intrapleural pressures are interfered with before the bleeding point is sealed off a fresh haemorrhage may be caused, whereas, if left for too long, organization of the blood clot is likely to commence and permanent damage may result. It would appear that an interval of about a week is desirable before the blood is removed. It is interesting to note that in this case the blood seemed to be entirely liquid and there was no evidence of the presence of a mass of fibrin; it was possible to empty the pleural cavity so completely that the film taken three weeks later did not show any trace of residual blood or of pleural thickening.

A recent French Government decree brings into existence the Order of Public Health which is to be awarded to persons who have distinguished themselves in the promotion of health and infant welfare. Of the three grades within this Order the highest is that of Commandeur. The next is that of Officier and the third is that of Chevalier. The decree specifies the conditions under which this honour is to be awarded. It is to replace the honorary medals hitherto conferred on persons distinguished in the field of public health.

## EXTRA-UTERINE GESTATION LIVE CHILD

BY

FRANK STABLER, M.D., F.R.C.S., M.C.O.G.

*Honorary Assistant Obstetrician Princess Mary Maternity Hospital Newcastle upon Tyne*

(WITH SPECIAL PLATE)

Sittner in 1906 collected all the records from the year 1809 of extra uterine foetuses which showed any signs of life and later Hellman and Simon (1935) brought these up to date. In the 126 years 266 such records were tabulated. Hellman and Simon's tables include many cases where the child was not viable and I have rejected these cases. Of the 266 women 179 recovered, eighty-four died and of three the fate is unknown. Of the 266 babies 152 lived for eight days or more, 113 died within this period and of one the fate is unknown. According to Hellman and Simon's abstract in only eighty cases did mother and child survive but I find that this figure should be 110. Probably the authors rejected some cases where the child died later but as all of them will eventually die I have adhered to the standard of survival for eight days. Twenty-eight of the 266 babies are recorded as being deformed to some extent, and of these sixteen lived eight days or more. These figures are probably valueless as evidence of the likelihood of survival for there is a greater tendency to record successful cases than unsuccessful ones.

Since Hellman and Simon's publication Zarif (1935), Krishnan (1936), Futh (1936), Wilson (1936), Woods (1936) and Anderson (1936) have reported cases. It seems to be well established that if the removal of the secundines is difficult or dangerous they may safely be left inside the abdomen, even to the whole placenta and membranes. In the case here recorded removal of the placenta was fairly easy but a great deal of the membranes was left without any harm resulting. Marsupialization with its subsequent sepsis is unnecessary. I have known of a twin placenta which disappeared from the peritoneal cavity in a period of nine months.

## Case History

A woman aged 25 was referred by Dr A. C. H. McCullagh of Bishop Auckland on September 14, 1937, on account of persistent transverse lie. She was an unmarried primigravida and gave a history of amenorrhoea since January 6 which suggested term about October 13. On May 8 she had pain in the left lower abdomen which kept her in bed for a week. She returned to work on May 15 but on May 20 had a sudden intense pain and was in bed for a further fortnight. Movements were felt for the first time at the end of May and since then they had caused her pain which increased in severity as pregnancy advanced. Vomiting began at this period, later becoming worse.

On admission she was wasted and very ill, having a temperature of 97.4 F and a pulse rate of 124. The urine was loaded with acetone but contained no other abnormal constituent. There was pain of a colicky nature in various parts of the abdomen, severe enough to make her roll about the bed and shout, and there were intervals of vomiting. Examination showed the foetus to be lying transversely with the head in the right lumbar region. The foetal parts and movements were unduly easily palpable whilst in the left iliac region was a smooth rounded mass the size of a five months pregnancy. There was considerable hydramnios. Contractions could not be felt over the foetus or over the smooth mass. Per vaginam a fluctuant bulging of the posterior fornix was palpated and the cervix appeared to be connected with the

mass (though later this was revealed as the placenta outside the uterus). Dr D. Ramage took radiographs which showed a normal foetus with in addition a clearly marked oval mottled shadow—half the size of the foetal head—in front and to the right of the first lumbar vertebra (Special Plate Figs 1 and 2). This shadow was unexplained even at operation, but a post-operative radiograph showed it in the rectum and I later received confirmation from her own doctor Dr A. H. Wardle of Bishop Auckland that she had been receiving a bismuth mixture. The radiograph, as taken three days after any bismuth had been given. In the four days before operation her bowels were moved only by enemata and there was considerable gaseous distension of the abdomen. The day after operation her bowels moved repeatedly and the distension ceased. A pre-operative diagnosis of third trimester extra-uterine gestation with hydramnios and intestinal obstruction was made.

On the day of operation she was so ill (pulse rate 100) that general anaesthesia was deemed inadvisable and at 2.10 p.m. on September 18, she was given morphine subcutaneous and hyoscine hydrobromide 1/100 grain hypodermically. At 2.40 p.m. a large Spencer Wells forceps was passed through the cervix for three inches, confirming the opinion that this was not an intra-uterine gestation. With 1 per cent procaine infiltration anaesthesia a midline subumbilical incision was made. The upper 10 inches of the incision revealed tanned "wash leather" yellowish grey amnion and the incision was rapidly extended a further 10 inches above the umbilicus. On opening the membranes a large quantity of liquor was estimated at six to eight pints escaped. The child was extracted as a breech and breathed immediately. It was a female weighing 5 lb 4 oz and showed some lateral flexion of its body and a mild right sided calcaneo-valgus. Both the feet were of a temporary nature and disappeared in twenty-four hours; they would have passed unnoticed in a normal delivery. The membranes were adherent above to the distended small and large intestines and to the omentum but there was no evidence of a talerac where it was possible to strip off the membranes; the naked adjacent structure was left beneath. In front the membranes lay against the anterior abdominal wall and below they covered the bladder and filled the pouch of Douglas, leaving the placenta projecting up into the sac. By separating some omentum access was gained to the general peritoneal cavity and it was found that the placenta was attached solely to the left broad ligament of ovary and tube close to the uterine cornu. The outer half of the left Fallopian tube was outside the sac and appeared normal. The uterus was surprisingly small, being equivalent to a 3 months pregnancy. Removal of the placenta, which showed a haematoma the size of an egg, close to the cord on the foetal aspect was not difficult and needed but three clamps; one clamped the ovarian vessel, one the round ligament and one the ovarian ligament and uterine cornu. There was not much loss of blood. A little nitrous oxide and oxygen was administered during the clamping of the pedicles. About 1/2 of the membranes was removed by tripping, but it was found that this caused some capillary oozing, so the part remaining on the bladder, bowel, pouch of Douglas, omentum and anterior abdominal wall was left *in situ* and the abdomen closed without drainage. At the end of the operation the general condition was quite good though the pulse rate was 170. The patient was returned to bed and a pint of 5 per cent glucose in normal saline was slowly introduced intravenously.

On the following day there was a considerable degree of ileus. Five units of posterior pituitary extract with 1/100 grain of eserine sulphate were given hypodermically followed by a further five units after half an hour. Her bowels moved at least eight times and from then on she made a rapid recovery, only delayed by the dressing of a small area of the wound which required three stitches. The temperature was never above normal and the foetus remained the pulse rate was 80. She left hospital five weeks after operation in good condition. The baby was fed artificially and was thriving for a while, developed an enteritis and was transferred to the Newcastle Babies Hospital under the care of

Dr J C Spence The mother later took charge of the baby, and when it was four months old wrote to say that it was thriving and gaining weight

I have to thank the various medical men named for their co operation, and Drs J F Fraser and W F Hall for assistance at the operation

## Clinical Memoranda

### Complications of Gold Therapy

(WITH SPECIAL PLATE)

The following case showing complications of gold therapy may be of interest in view of the widespread and protean nature of the lesions. Among twenty-six cases given thirty-four courses this was the only one which showed a severe reaction, other complications being three of albuminuria and two of very localized dermatitis

## CASE REPORT

A fitter aged 31 had a septic finger with suppurating axillary glands in October, 1935. Five weeks later he began to have vague pains in his heels and subsequently in his knees, shoulders, wrists, and fingers. There was no history of rheumatic or scarlet fever in childhood. On admission to the Newcastle Royal Victoria Infirmary under Dr George Hall on January 11, 1936 his temperature was 100.6° F and his pulse 106, the affected joints were swollen and somewhat red. The gonococcal complement-fixation test was negative and a diagnosis of rheumatic fever was made. Treatment with salicylates was begun, and forty eight hours after admission the pulse and temperature were normal. He was in hospital for seven weeks, and on discharge continued radiant heat and diathermy, which he had had during the latter part of this time. Persistence of the pain in the heels led to a raying of that region, but with a negative result. When first seen by me in May, 1937, he still complained bitterly of pain in the heels, and to a less extent in the small joints of the hands. There was some tenderness on pressure over the heels and slight swelling of the finger-joints, but no heat or redness. Examination of the throat, teeth, sinuses, and urine revealed no evidence of a septic focus, and in view of the considerable discomfort the patient was suffering and the fact that he was very anxious to be restored to normal health before being married, it was decided to begin treatment with lipoion. A course as recommended by Hartfall and Garland (one 0.01 gramme dose, one of 0.025 gramme, one of 0.05 gramme, and nine 0.1 gramme doses) was given, and he remained well throughout. Pain began to improve about the middle of the course and disappeared before the end. His urine was free from albumin throughout. The patient was instructed to return in three months, when widespread lesions were observed to be present. He then stated that two weeks after the termination of treatment his mouth became sore, later his neck became dry (Plate, Fig 1), and his hair began to fall out two months later. His feet then peeled and nail changes were first noticed one week before his return.

On examination his general condition was good. The scalp showed a diffuse thinning, the patient having previously had a good head of hair. There was a diffuse dryness of the skin, with patchy purple lesions on the arms and heels like pityriasis rubra, the trunk showed a fine scaling, and the face a good deal of erythema with some scaling. The palate was the site of small superficial ulcers, and on the buccal surfaces of the cheeks were

sodden lesions not unlike lichen planus in that situation. The nails were in process of being cast, and the growth of new nails was apparent, the photograph reproduced on the plate (Fig 2) being taken some days later. Blood examination gave the following result: red cells, 505 millions, haemoglobin, 86 per cent, leucocytes, 15,000, reticulocytes, 0.4 per cent, platelets, 280,000. The capillary resistance test was negative after fifteen minutes pressure at 75 mm Hg.

When seen in January, 1938, the skin was much improved and the nails were growing again, but there was no improvement in the scalp. The patient remained free from pain in the heels or joints, and was well in his general health.

Since writing the above note I have again seen the patient. He attended on March 28, and I now find that the skin and nail lesions have completely cleared up and the hair is almost restored to normal.

I am indebted to Dr George Hall for permission to publish this case.

T H BOON, M.D., M.R.C.P.,  
 Newcastle upon-Tyne  
 Medical Registrar, Royal Victoria  
 Infirmary

### Bilateral Axillary Breasts

(WITH SPECIAL PLATE)

The photographs of an unusual case—that of a woman with a pair of axillary breasts—may be considered interesting enough to be reproduced here (see Special Plate).

The patient is a young woman, lactating, with her second baby, aged 2 weeks. Had the photographs been taken some ten days earlier the breasts, which were engorged, would have been seen to be larger still. Each breast is entirely separate from the normal pectoral breast below, and is provided with a small nipple, from which milk runs down the arm during suckling. The areola point towards these nipples. It is not unusual to see a vestigial breast or nipple on the pectoral line below the normal breast, but I believe a complete breast, with nipple, functioning in each armpit must be very rare.

Wang, N Z MOLLIE CHRISTIE, M.B., Ch.B.

### Ether Convulsions with Recovery

The occurrence of ether convulsions has aroused considerable interest recently, and although more and more cases of recovery after different methods of treatment are being reported I feel that one further case is worth putting on record.

## CASE REPORT

A male patient, aged 17, was admitted to the Western Infirmary, Glasgow, on December 16, 1937. His history symptoms, and signs were typical of acute appendicitis, the attack having begun twenty-four hours previously. At operation the appendix was gangrenous and had ruptured close to the wall of the caecum, pus and free fluid being found in the abdominal cavity. The appendix was removed and the abdomen drained. It was noted that the proximal part of the ascending colon, the caecum, and terminal ileum were injected and showed some small petechial haemorrhages. The administration of the anaesthetic—ethyl chloride followed by open ether—was uneventful. After the operation the patient vomited at intervals during the next five days, his temperature ranging from 98.3° F to 101° F and his pulse rate from 90 to 110 a minute, the respiration rate was 24 a minute. It was decided to operate again on December 22, 1937, and the abdomen was opened with a right paramedian incision. At this time the boy was very ill and very toxic, his colour was poor, his temperature 99° F, his pulse 96, and his respirations 24 a minute. Anaesthesia was induced with ethyl chloride and continued with open ether. Oxygen was flowing gently under the mask. The small bowel above the caecum was atonic and distended for a

considerable distance. An enterostomy tube was inserted just above the paralytic part of the bowel.

As closure of the abdomen was begun the house surgeon who was administering the anaesthetic called me over and drew my attention to twitching of the neck muscles. The mask was removed and the facial muscles were found to be twitching violently. The anaesthetic was discontinued and oxygen and carbon dioxide were administered. I prepared a solution of evipan sodium (10 per cent) and by the time this was ready vigorous convulsions had spread to the shoulder girdle and to both arms. They had begun also in the body and lower limbs but less violently though they were sufficiently severe to render closure of the abdomen more or less impossible. One arm was sufficiently controlled to allow of an intravenous injection of 34 ccm of evipan sodium being given; this was just the amount required to control the convulsive movements. The pulse at this time was very poor and the colour pale. Within a minute the pulse improved and with it the boy's colour. Closure of the abdomen was completed without further trouble or incident and no more evipan was required. Cold wet towels were also applied to the head and as a final measure 10 ccm of calcium gluconate were given intravenously.

The patient was returned to bed in fair condition and there were no further convulsive movements. His temperature was taken immediately he returned to the ward and was found to be 103 F. It rose in an hour to 104 F and was charted hourly for the next eight hours the readings being 103.8, 100, 101.8, 102.6, 103, 102, 102.4 and 102 F. Two hours later it was 99 F and although it rose later that day to 101.2 F further progress was at a more or less normal level.

#### COMMENTARY

The abdominal condition naturally caused some anxiety for a few days but the recovery from the anaesthetic was uneventful except for one curious complaint. The boy noticed on the morning following the operation that pulling his hair over the left occipito temporal region caused no sensation whatsoever a phenomenon which rapidly passed off and probably bears no relation to his ether convulsion. He has now made an excellent and complete recovery. I think it is fair to diagnose this as a case of true ether convulsions. The type of patient and his toxic condition the sudden onset late in the operation, the convulsions beginning typically in the face and neck muscles and spreading to the rest of the body and the rapid rise in body temperature make up the usual clinical picture. Chadwick reported a case of recovery after the use of evipan in the *Journal* (1936, 1, 1253) and I have no doubt there have been other recoveries following this treatment since then. Bamford reports five cases recovering after compression of both common carotids simultaneously for five seconds with raising of the head of the patient and lowering of the feet. Cessation of the convulsions has also been reported after the intravenous injection of calcium gluconate (A. S. Hoseason *Brit J Anaes* 1936, 13, 142). Had I known that calcium gluconate was immediately available on this occasion I would have injected it while the evipan was being prepared instead of afterwards when the convulsions were under control. Confirmation (in another case) of the above result would have been very interesting, and would have lent further support to the theory that the condition is due to neuromuscular irritability following diminution of the physiologically active fraction of the serum calcium.

For permission to publish a record of this case I am indebted to Mr M. Logan Taylor to whose wards the case was admitted and to Mr R. S. Kerr and Mr A. I. L. Maitland who performed the two operations.

HERBERT H. PINKERTON, M.B. Ch.B.  
Anaesthetist, Western Infirmary

## Reviews

### THE THYROID AND ITS DISEASES

*The Thyroid and Its Diseases* By J. H. Means, M.D.  
(Pp. 602, 22s net) Philadelphia and London: J. B. Lippincott Company, 1937.

Although Magnus Levy demonstrated in 1895 the role of the thyroid in gas exchange it was not till twenty years later that the determination of basal metabolic rate emerged as a means of measuring quantitatively the level of thyroid function. Metabolic rate estimations were begun at the Massachusetts General Hospital in 1913 and round the metabolism laboratory as headquarters the Thyroid Clinic has developed. Since the war much clinical and research work has been carried out and with the object of defining the present state of knowledge of the subject Professor Means has been led to write a book on *The Thyroid and Its Diseases*. He has marshalled the facts in a masterly manner and deals openly and judiciously with controversial matters. The first hundred pages are taken up with a discussion of the anatomy, physiology and pathology of the gland and the general symptomatology of its diseases. The nature and degree of the morbid process are assessed through observing signs and symptoms and through measuring bodily functions. Of these the determination of the metabolic rate is of special importance. Some of the newer lines of study—creatin tolerance, iodine and thyroxine content of the blood, thyrotropic hormone content of blood and urine and electrical impedance—may further extend our knowledge. Professor Means and his colleagues have not found much gain from study of the electrical impedance. Viewed broadly the pathology of the thyroid separates itself into a group of morbid processes which may afflict the thyroid much as they do any other organ or tissue—congestion, inflammation and new growth—and a group of morbid processes which are peculiar to the thyroid and have their being in its special structure and function. The latter resolves itself on the functional side into states of increased or decreased secretory activity and on the structural side into hyperplasia on the one hand and hypoplasia, destruction, ablation and atrophy on the other.

In the absence of known aetiology of many of the thyroid disorders classification is unsatisfactory but some sort of classification is necessary to facilitate the study of cases and clarify the indications for treatment. The so-called simple goitre is a well recognized entity due to iodine deficiency where the clinical picture is dependent upon an insufficient production of hormone. Hypothyroid states occur and Professor Means prefers the term toxic goitre to cover all those states of hyperthyroidism comprising thyrotoxicosis, exophthalmic goitre, Parry's Graves' and Basedow's disease. He believes that there is no reason to differentiate two sorts of toxic goitre—exophthalmic and Plummer's toxic adenoma—other than that the type of toxic goitre does not determine the iodine response which in all thyrotoxic patients is essentially the same. The similarity of response is an argument in favour of the essential unity of toxic goitre as a class. The author deals with simple goitre and the hypothyroid states—myxoedema, juvenile myxoedema and cretinism—on a theoretical and satisfactory basis especially urging the distinction between juvenile myxoedema and

disease acquired during childhood, and true cretinism, which is congenital, for the prognosis and factors governing successful treatment are different. There is, too, a distinction to be made between endemic and sporadic cretinism. In the case of cretinism it is pointed out that the success of treatment depends upon the time of life at which it is begun and the adequacy with which it is maintained. Especially in the sporadic cases should the attending physician be alert to detect it early and carry out treatment promptly and persistently.

The iodine response in toxic goitre is one of its characteristic features. An amelioration of all symptoms usually begins in a few hours, and the metabolic response runs parallel, its magnitude and rate can be predicted with fair accuracy. It takes about ten days to reach its completion—that is, to get the patient fully iodinated. Anatomically there is diminished congestion of the gland and involution occurs, there is increased storage of colloid and the epithelium returns to a state resembling the resting. Apparently iodine obstructs the delivery of hormone from the thyroid, but the morbid stimulus to the gland continues to work. The minimum dose of iodine which will produce the full characteristic response is about six milligrammes a day. Larger doses are usually given, as there is no objection and the risk of underdosage is eliminated. Iodine administration is a necessary part of preparation of the thyrotoxic patient for operation. In no toxic case should an operation be done until the patient is fully under the influence of iodine. Iodine is very effective in the control of the milder forms of thyrotoxicosis residual to or persistent after operation. Indeed, in specially selected cases it may be enough to use iodine as a treatment by itself. Such cases are a very small proportion of the total, and in Professor Means's series over the years 1932–5 inclusive amounted to but 1.3 per cent of the whole. X rays are an effective form of treatment in some cases, but subtotal thyroidectomy in the fully iodinated patient is at the moment the best treatment that can be offered. It gives a better chance of prompt and permanent cure than any other therapy now available. In cases coming to operation the importance of adequate preparation, careful anaesthesia, and team-work among the surgeons is emphasized. There is much to be said for preferring the slow, careful, bloodless technique which preserves the parathyroids and nerves by exposing and avoiding them. There are various complications of toxic goitre—cardiac insufficiency, the so-called toxic storms, psychoses, and glycosuria—which crop up in large series of cases in sufficient numbers to allow of generalization. The whole class of nodular, adenomatous goitres is in an entirely different category, their treatment is guided by the presence of thyrotoxicosis, of tracheal compression with pressure symptoms, or of any features suggesting malignancy. Malignant goitre is not rare, and can be cured only by early treatment.

The remaining chapters of this most interesting and instructive book deal with anomalies of the thyroid, thyroid administration in diseases other than those of thyroid origin, and the possibility of affecting the course of other diseases by total thyroidectomy. Readers will find Professor Means's book a mine of information, compiled with judgment and offering a statement of our knowledge which conforms with the most advanced thought of present-day medicine. The author is to be congratulated on the open-mindedness of his conclusions, and he would be the first to acknowledge, indeed to expect, that many of them will be modified as the result of further work.

## PLANT VIRUS DISEASES

*A Textbook of Plant Virus Diseases* By Kenneth M. Smith. D.Sc. Manch. Ph.D. Camb. (Pp. 615, frontispiece, 101 illustrations. 21s.) London: J. and A. Churchill Ltd. 1937.

Dr Kenneth Smith has produced another book on plant viruses, and this one, as its title implies, is concerned with the diseases which these agents produce. Naturally it is not a book which will appeal to the general medical public, it is not intended for them, but for the plant pathologist. And for the same reason it is quite impossible for anyone not possessed of a knowledge of plant diseases to review such a book critically. All that can be done is to give some idea of its scope and to take the facts on trust, seeking comfort in the thought that the author's eminence in this branch of plant pathology is ample guarantee of the book's factual content. One gathers from the preface that Dr Smith was at some pains to arrive at a satisfactory method of classifying these plant viruses. Eventually he decided on the plan of naming them after the host plant most commonly affected—using the Latin and not the popular name—and numbering the different viruses attacking the same host. Thus tobacco mosaic virus becomes *Nicotiana virus 1*, speckled tobacco mosaic *Nicotiana virus 2*, and so on. This method appears to work quite well, and arranged in this way the various plant viruses and the diseases they produce are described according to a common plan. The first part of each section is devoted to a consideration of the characters of the virus, its mode of transmission and its host range, while the second part is concerned with the diseases caused by the virus and such important questions as the geographical distribution of these diseases and their control. Chapter VIII is concerned with the insects responsible for the transmission of these virus diseases, and it constitutes a very valuable portion of the book. The last chapter contains brief references to plant diseases suspected of being of virus origin, and the book closes with an appendix in which the most characteristic symptoms of the various diseases on their more important host plants are given in tabular form.

The book is well printed, contains numerous illustrations, and has both a subject and an authors index. In addition a list of references is appended to each chapter which cannot fail to be of value.

## PHYSIOLOGY

*Physiology in Modern Medicine* By J. J. R. Macleod. Eighth edition. Edited by Philip Bard. (Pp. 1,051, 355 figures, 103 tables. 36s. net.) London: Henry Kimpton. 1938.

The seventh edition of the late Professor J. J. R. Macleod's *Physiology in Modern Medicine* appeared in 1935 shortly before his untimely death. That an eighth edition should have been called for so soon is in itself a testimonial to its usefulness in the past, but with the author's decease his book has suffered a change. Professor Bard, the new editor, indeed states that "little of the seventh edition remains. The greater part of the book has been entirely rewritten, and that by nine individuals. With the great growth of physiology this may be inevitable but nevertheless regrettable. Even in the last edition of Michael Foster's *Textbook of Physiology* much preparatory work was done by others, but the whole bore the imprint of his mind, as unmistakable as the brush-work of an old master. This is hardly possible to-day. But this book

has undergone a further change its original purpose was to serve as a guide to the clinical application of physiology and biochemistry. The present edition makes no pretence of being a textbook of applied physiology. Nevertheless the title is retained because in the editor's opinion the greatest service which physiology can render modern medicine is to continue to solve fundamental problems which are not necessarily of immediate practical concern. The original *raison d'être* of the book therefore seems to have vanished and it must compete with other textbooks of general physiology. Judged by that standard it appears to be a thoroughly competent piece of work while leaving room for another to fulfil the author's original purpose.

## X-RAY EXAMINATION OF THE LARYNX

*Methodik der Röntgenuntersuchung des Kehlkopfes* By Dr Richard Waldapfel (Pp 91 77 figures RM 17 60 bound RM 19 60) Leipzig Georg Thieme 1938

Dr Waldapfel thinks that the majority of laryngologists have not appreciated the work of Thost upon the examination of the larynx with Roentgen rays partly because they believe this is unnecessary and partly because of the indifferent results. He is convinced of its value in the diagnosis of gross disease of the larynx both in demonstrating the nature of the morbid process in such conditions as perichondritis and tuberculosis and also in delineating the precise extent of tumours. His work is magnificently illustrated with diagrams and reproductions of radiographic films and is a convincing proof of the diagnostic value of the method. To those anxious to acquire the technique and to those interested in the interpretation of the results this book can be recommended without hesitation.

## BIOLOGICAL WORKS OF ARISTOTLE

*Parts of Animals Movement of Animals Progression of Animals* By Aristotle Translated by A L Peck MA PhD and E S Forster MA With a Foreword by F H A Marshall CBE ScD FRS (Pp 376 Cloth 10s net leather 12s 6d net America Cloth 2.00 dollars leather 3.50 dollars) London William Heinemann Ltd Cambridge Massachusetts Harvard University Press 1937

This is the fifteenth volume of the works of Aristotle published in the Loeb Classical Library and there is still the *De Coelo* to come. It is clear therefore that the great master is still read although Greek is no longer compulsory. The present volume contains the biological treatises the *De Partibus* the *De Incessu* and the *De Motu Animalium*—treatises which have always appealed to the most cultured minds in the medical profession for they deal with biology with anatomy and with physiology. How and where Aristotle got his immense knowledge is not known. Whales are not common in the Mediterranean yet he recognized that they were not fish but were in a way land animals and water animals they inhale the air like land animals but they have no feet and they get their food from the water as water animals do. The gall bladder too interested him and he knew the creatures which possess gall bladders and those in which they are wanting though his reason for the presence or absence no longer holds good. The essay on the parts of animals is introduced by Dr F H A Marshall FRS Reader in Agricultural Physiology Dr A L Peck University Lecturer in Classics at Cambridge provides an excellent translation in which he acknowledges his indebtedness to the

scholarly version made some years ago by Dr William Ogilby. Mr E S Forster Professor of Greek in the University of Sheffield translates *The Movement of Animals* and *The Progression of Animals*. There is an excellent introduction and an index which is good when one has learnt how to use it. A perusal of the treatises enables the reader to understand why he fascinated such minds as the wizard Michael Scot Robert Grosseteste the greatest of the Bishops of Lincoln and Dr William Harvey who in his *De Generatione* continued Aristotle's work on embryology.

## Notes on Books

*The Management of Early Infancy Puberty and Adolescence* (C W Daniel Company Ltd 2s 6d) is one of the pamphlets issued by the Medical Society of Individual Psychology. Dr Joyce Partridge deals with the management of early infancy Dr H Crichton Miller with puberty and adolescence Dr T A Ross with the psychological approach and the late Dr Crookshank with the neurotic character—a lecture which has been put in to take the place of one of the series on child psychology which was not available. These papers are popular and sufficiently interesting but with nothing very original about them except perhaps Dr Crichton Miller's observation that boys and girls approach puberty with different outlooks so that the former are prone to anxiety states and the latter to hysteria.

The little work entitled *The Healthy Heart and the Diseased Heart* (Rome Istituto Nazionale di Assicurazione 5 lire) is as its subtitle—*A Doctor's Advice*—suggests a popular work which was intended primarily for the members of the Italian Insurance Institute instructing them how to collaborate with the doctor in the prevention and treatment of heart disease. Sound advice is given as regards diet rest occupation tobacco alcohol climate sport travel housing personal hygiene sleep marriage choice of profession and recreations.

*Mothercraft Antenatal and Postnatal* (J and A Churchill 10s 6d) has been prepared for a second edition by Dr REGINALD C JEWELL and it has sections on bottle feeding but excepted (because of their rigid insistence on percentage feeding) it can be highly recommended to practitioners as a guide to the management of infants. The section on the premature baby is particularly good.

Professor ALBRECHT PEIFER'S original contributions to the premature baby are well known and it is therefore a great pleasure to welcome his monograph on immaturity and debility (*Unreife in d Lebensschwäche* Leipzig Georg Thieme RM 6 80). This summarizes recent work especially of his compatriots on small and premature infants and within brief compass gives an excellent presentation of the subject.

*Bienenstift als Heilmittel* by Dr ROBERT SCHUBERT (Leipzig Georg Thieme RM 2 40) is a monograph on the treatment of rheumatic diseases by bee venom. After discussing the history of this treatment which goes back to the earliest days the author deals with the mechanism and mode of action of animal poisons in general and of bee venom in particular and with the methods by which the venom may be extracted. The pharmacology of bee venom is dealt with in detail. The author then discusses the relation between the immunity so produced and its therapeutic action in rheumatism. Finally the indications or application of the various preparations of bee venom in the treatment of different forms of chronic rheumatism neuralgia and neuritis are dealt with. A bibliography is included.

Under the title of *The Eruptive or Exanthematous Mediterranean Fever* (Rome Luigi Pozzi 18 lire) Dr CARLO COSTANZI assistant director of the Policlinico Umberto I at Rome and assistant to Professor Agostino Carducci, who contributes the preface, gives an excellent description of this disease, which is known as summer typhus or boutonneuse fever and was first described by Conor and Bruch in 1910. The text is interspersed with photomicrographs and illustrations, and a bibliography of 166 references is appended.

## Preparations and Appliances

### PORTABLE OPHTHALMIC TESTING UNIT

Dr J HORTON YOUNG (Assistant Medical Officer for Eye Diseases Wolverhampton) writes

I have designed a portable ophthalmic testing unit which may be used for testing visual acuity, for Worth's binocular test and for objective examination of the eyes, as in retinoscopy or ophthalmoscopy. This portable unit is divided into two parts—the carrying case, equipped with handle, lock key and four slide racks to carry extra test types, etc. and the actual testing unit. This may be removed from the carrying case when tests for visual acuity are being done or may be left in the case when it is desired to do Worth's binocular test or to make an objective examination of the eyes. The testing unit itself is internally illuminated and revolvable on a hollow boxed base. The revolving drum, which is freely movable and smooth in action carries four test types (children's and Snellen's standard types 6/60 to 6/45). The retinoscopy or the Worth's binocular test diaphragms may be substituted for the opt test types as required. The hollow box base carries flex, a two-way plug, and a triple faceted power plug, so that it can be plugged into any alternating electric power source. There is also room in the hollow base for Morton's non luminous ophthalmoscope, condensing lens, and loupe.

The weight of the combined testing unit is 13½ lb and the overall dimensions of the carrying case are 14½ inches by 10½ inches by 8½ inches. The instrument has been designed primarily for school medical officers but may be used in hospitals for those patients who are unable to leave the ward. I am indebted to Mr Rogers, lecturer in handicraft at the Bushbury Hill School for technical advice and the actual construction of the instrument. Messrs F Davidson and Co of London whose courtesy enabled me to obtain the necessary standard opt test types to specification, state that they would be prepared to make a similar instrument for any other medical officer who may require one.

### SPLINT FOR INDWELLING CATHETERS

Mr JOHN GROCOTT F.R.C.S. (Stoke-on-Trent), writes

Having had many unfortunate experiences with indwelling urethral catheters I attempted to discover a simple yet efficient retaining mechanism. Tape and strapping and sutures and strapping have two main faults: (1) the external meatus and adjoining catheter cannot be kept sterile and (2) the soft rubber catheter tends to curl and to be extruded through a

gap between the tapes. This second difficulty can be overcome by the use of a stiff gum elastic catheter in place of the usual soft rubber variety, but additional urethral trauma is caused by the stiff catheter and it soon becomes incredibly filthy. Other methods as by using rubber bands with studs, have in my experience been worse than useless and decidedly uncomfortable for the patient. I therefore devised a metal splint made of 18 gauge aluminium sheet. The splint is in reality a straight double trough, which can be made in a few minutes.

The splint is sterilized by boiling and applied after catheterization with a soft rubber catheter. From the illustration above it will be seen that there is a gap between the splint and the catheter as it emerges from the penis. This gap can be packed with sterile vaseline gauze and kept completely sterile by covering it with zinc oxide strapping. When the splint is in position the whole is strapped in a continuous spiral from the root of the penis right on to the catheter. This makes a completely airtight joint of penis to catheter and sterility is assured. I have used this method of strapping with complete success. On no occasion has the catheter slipped out and what is more important it seems to be almost an impossibility for a uraemic patient to pull it out. Another advantage is the absence of any marked urethritis even after the catheter has been *in situ* for at least eight days. The splint is very comfortable, and providing the edges of the aluminium are quite smooth no chafing of the penis occurs. The removal of the splint is easy, cleaning and resterilization are very simple, and—an important fact—these splints could be manufactured in varying sizes for only a few pence each.

### NICOTINIC ACID B.D.H.

This relatively simple substance ( $C_6H_5NCOOH$ ) is stated to be the precursor of the pellagra preventing factor in the vitamin B complex, and is now prepared and issued for clinical trial. The dose suggested by British Drug Houses, Ltd is 30 mg by mouth twice daily. Clinical trials in the U.S.A. indicate that nicotinic acid has a dramatic curative action in pellagra. This action will doubtless be investigated intensively in the near future in all countries afflicted with pellagra, and there is in addition the chance that accessory actions may be found which are of service in other diseases.

The introduction of nicotinic acid for clinical trial completes a curious circle, since it was the first substance isolated from the vitamin B complex. This was achieved by Casimir Funk in 1913, and he suggested that 'vitamine B' was nicotinic acid. Research developed along other lines. 'vitamine B' became the vitamin B complex, a series of factors were identified, but nicotinic acid appeared to be of no significance and was almost forgotten. Now at last it has been found to be one of the most important of all the factors in the complex mixture of chemicals that originally was labelled 'vitamine B'.

### A TAR APPLICATION

Tar dermament (Messrs Parke Davis and Co) is a solution representing 6 per cent washed crude coal tar in a mildly analgesic resinous base. It is recommended for a variety of cutaneous disorders such as psoriasis and pruritus.

The simple extension apparatus described by Mr M. D. Sheppard in the *Journal* of March 26 (p. 677) is manufactured by Body's Pharmacies Ltd, 1 Moulsham Street, Chelmsford.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 9 1938

FACT AND FANCY IN MATTERS  
THYROID

With this arresting heading Professor J. H. Means opens the concluding chapter of his excellent book on the thyroid and its diseases which is reviewed elsewhere in this issue (p. 781). The thyroid is an internal secretory gland. Its sole function is elaborating and storing its own peculiar hormone and no other substance can take the place of the hormone in the organism deprived of its thyroid. In the colloid of the thyroid there is a protein (thyroglobulin) which owes its peculiar chemical and physiological characteristics to its content of two iodine-containing amino acids. The thyroid alone appears to possess the means of adding iodine to the tyrosine molecule: the iodine-containing amino acids so formed combine with other amino acids to form thyroglobulin which is stored as colloid. One of these amino acids has been prepared synthetically—thyroxine—and was at one time regarded as the thyroid hormone but the evidence goes to show that the activity of thyroglobulin is much more closely related to its total iodine content than to its thyroxine content. The active substance may be a peptide intermediate between thyroglobulin and thyroxine: anyway its action appears to be specific. Iodine then is necessary for the proper function of the thyroid. When there is relative or absolute iodine want hypertrophy of the gland occurs—simple goitre—which may be followed by atrophy when the deprivation continues, or may regress to normal if iodine is given. Hyperthyroidism or toxic goitre too responds in a remarkable way to administration of iodine. There is a striking amelioration of symptoms and reduction in the basal metabolic rate accompanied by involution changes in the active thyroid cells. In both instances the effect is due to the action of iodine on the gland substance altering its function of delivering hormone to the body. In thyrotoxic patients iodine appears to obstruct the delivery of hormone from the thyroid at any time during the course of the disease. But the morbid stimulus to the thyroid continues to work. Professor Means summarizes the position by using an analogy. Giving iodine in toxic goitre

may be likened to putting on the brake in a running motor car without changing the position of the accelerator. The brake is iodine: the accelerator is the cause of thyrotoxicosis. Iodine therefore has no effect on the duration or direction of progress of the disease: it affects at any one time merely its intensity.

The thyroid function thus is linked with the metabolism of iodine in the body. The thyroid hormone is necessary for the growing organism and in its absence the normal development of the body is retarded. In the adult too the thyroid hormone functions by regulating and stimulating the metabolic rate. In the toxic states of exophthalmic goitre it was thought at one time that there was something more active than excess of thyroid hormone and it was assumed that a chemically different hormone was excreted into the blood producing a state of dysthyroidism. A modification of this theory is that while excess of the normal thyroid hormone produces the increased metabolic rate, sweating, tremor and nervous state, a second hormone from involuting thyroid lobules (hormone of degeneration) is responsible for the cardiac symptoms: rapid heart beat and myocardial degeneration. There is no need to assume that there is more than one thyroid hormone or to differ from the view which Moebius stated long ago that states of hypothyroidism or myxoedema are due to insufficiency of thyroid hormone and of thyrotoxicosis (Graves's disease, Basedow's disease) to excess of this hormone being excreted into the blood. In thyrotoxicosis it is the same hormone but produced in excessive amounts by the actively secreting thyroid.

The cause of thyrotoxicosis—the stimulus to excessive function of the thyroid—must be sought therefore outside the thyroid. The earliest theory was that it was a nervous state and one aspect of permanent fright of the exophthalmic goitre patient was adduced as evidence of excessive nervous excitation. Abnormal stimulation from the periphery was suspected but the increased perfusion rate of the tissues and the increased oxygen usage are really the results and not the cause of excess of thyroid hormone in the blood. Recent work has shown that a functioning anterior lobe of the pituitary gland is essential for the normal development and function of the thyroid. The secretory tone of the normal thyroid is kept up by a continual stimulation from the anterior pituitary by means of its secretion—a thyrotropic hormone. When pituitary support of the thyroid is withdrawn the latter continues to function but at a reduced rate and excessive function of the anterior lobe causes the most intense activity of which the thyroid is capable. The increased metabolic rate now

ness, loss of weight, and tachycardia occur in animals in which extract of anterior lobe is injected, and the effect is through the medium of the thyroid, since it does not occur after removal of the thyroid gland. But it is believed that even the pituitary control of the thyroid is within limits, that it is relative, not absolute. Indeed Cope in a recent investigation<sup>1</sup> failed to find evidence that the anterior pituitary gland is usually responsible for the hyperthyroidism of primary Graves's disease. He found the serum of patients with Graves's disease had a depressant rather than a stimulant effect on the thyroid glands of guinea-pigs, and interpreted this finding as evidence against thyrotropic hormone (anterior lobe) being present in excess in the blood serum, rather that the depressant action is due to excessive thyroid hormone in the blood. It is known that thyroxine and thyroid hormone have an inhibitory effect on thyroid secretion. Other workers too have found no evidence that in human thyrotoxicosis there is an increase in thyrotropic hormone in the blood. Nor on clinical grounds is there anything to suggest adrenocortical failure in toxic goitre. A constitutional factor has been postulated, cases of hyperthyroidism occur in families. Since at the onset of so many cases emotional and stress factors are found, hyperthyroidism has been linked back to the hypothalamus and to control by the sympathetic. The thyroid gland itself is plentifully supplied with nerves, both sympathetic and parasympathetic. Within the gland the nerve fibres form dense plexuses—a vascular plexus and an interfollicular plexus, with many communications between the two. These nerves must take some part in the regulation of secretion and storage through the medium of the blood vessels, though evidence is lacking of direct stimulation of parenchymal cells by way of nerve fibres.

Subtotal thyroidectomy in the fully iodinized patient offers at present the best means of dealing with thyrotoxicosis, though removing the thyroid gland does not remove the cause of the condition, which is almost certainly extrathyroidal. Pemberton makes the point that subtotal thyroidectomy must have some more far-reaching effect than merely reducing the output of thyroid hormone, since if the causative factor continues to operate recurrence would be common, and this is not so. Operation may so reduce the amount of thyroid hormone as to break some vicious circle of causative factors, thus allowing in many instances permanent restoration of the patient to a state of health. Nevertheless the present-day treatment will not be, we may hope, the ultimate treatment.

## ELECTRICAL INTERFERENCE WITH WIRELESS RECEPTION

The British Medical Association has lately had under discussion the effect of possible future legislation on the users of various forms of electro-medical apparatus. The object of such legislation would be to suppress excessive interference with broadcasting and other wireless services from various electrical devices, including the appliances used in medical diagnosis and treatment. Whereas the interference caused by generators of galvanic, faradic, and sinusoidal currents can be eliminated by simple and cheap methods, this is not so in the case of diathermy and short-wave machines, which produce etheric disturbances of the same nature as wireless waves. There are two ways in which such interference might be minimized. First by effectively screening the apparatus and patient, and, secondly, by the allocation of certain wave bands, coupled with legislation prohibiting the use of apparatus that does not conform to the requirements.

The cost of effective screening and providing the necessary filters is estimated at £15 to £20 for a room 12 ft × 16 ft × 8 ft high. Having regard to the varied applications of high-frequency currents in the field of medicine and surgery and their special branches, and the varying conditions of practice, screening is in some cases impracticable, and it has been pointed out that to restrict facilities for treatment by electrical methods would be a retrograde step and against the public interest. The apparatus often has to be taken to the patient and not the patient to the apparatus. To comply with the requirements it might thus become necessary to convert certain sections of hospitals or nursing homes, including operating theatres, electro-therapeutic departments, and special wards, into "Faraday cages," and as this would be impossible where the patient's own home is concerned the use of such apparatus in the patient's home might have to be prohibited unless certain specified frequencies were used. Under this alternative method the difficulties, though great, are not insuperable. The reservation of certain bands and the restriction of certain types of apparatus which cause undue interference to certain definite regions is at least a practicable proposition if suitable bands could be determined. Two important questions arise under any such scheme. In the first place it is possible that the definition of the optimum band might have to be modified if it could be shown that better results were obtainable by the use of different wave lengths. Research is at present being carried out, particularly on the Continent,

<sup>1</sup> Cope, C. L. (1938) *Quart. J. Med.* 31, 151

into the effect of different wave lengths in different diseases but no definite conclusions have yet been published. Provision should be made however for any decision as to the most suitable band to be reviewed in the light of further research. Secondly if the use of electro-medical apparatus were restricted as suggested what arrangements could be made for the carrying on of research on lines such as have been indicated above? In this connexion it is probable that some form of screening might provide a solution of the difficulty.

Discussion has taken place between the Government Departments concerned and the professional interests chiefly affected but the British Medical Association would welcome the opinion of any who are interested or who can suggest further methods of dealing with this important problem. It has been suggested that appropriate reservations might be made in the following regions: medium wave 100–200 metres, short wave 10–100 metres and ultra short wave 2–10 metres. A preliminary survey indicates that waves in the neighbourhood of 150 metres, 30 metres and 6 metres might be satisfactory for medical purposes, provided that suitable provision can be made both for research and for revision in the light of further experience. There is considerable doubt whether these particular waves could be allotted but it is possible that a band of 30 kc round about 110 metres and frequencies in the neighbourhood of 2 metres may be available.

The matter plainly deserves serious study. On November 10 last year the Postmaster General was asked in the House of Commons whether he could give an assurance that the necessary legislation to deal with the question of electrical interference with broadcast reception in this country would be introduced during the current session of Parliament. While he was unable to give the assurance that a Bill could be introduced during this session, he said that the proposals to be embodied in a Wireless Telegraphy Bill to deal with the question of electrical interference with broadcast reception in this country were being actively pursued. Readers having information to give should send it to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

### WHAT IS GOUT?

It may seem strange that in the twentieth century such a question can be put concerning a disease known to Hippocrates and graphically described by Sydenham. Apart however from the characteristic acute outbreak in the great toe and the implication of other joints in a similar manner in the later stages there has always been a tendency to

regard other morbid states occurring in patients who have suffered from the acute form as being necessarily of the same origin. We have for example been led to believe in such conditions as gouty iritis and gouty phlebitis. If the patient suffering from iritis or phlebitis has had acute gout at a previous stage in his history it may be difficult to prove that they are not associated with a similar metabolic derangement. Often however the adjective gouty has been applied to such disorders because of their superficial resemblance to cases clearly of gouty origin or because they have appeared in persons of plethoric aspect, thus many ailments and especially those affecting joints and muscles have been diagnosed and treated as gouty in the absence of any stronger evidence. The terms irregular metastatic and retrocedent gout—less often heard nowadays—were used to describe disorders attributed to gout but which had actually no relation to the derangement of purin metabolism which was so ably and clearly described as the basis of gout by Sir Walter Langdon Brown in opening the discussion on this subject at the International Congress on Rheumatic Diseases at Bath last week.

The exact part played by uric acid itself in the production of gout, symptoms is still far from clear but it may safely be said that gout is associated with an excess of uric acid in the blood and its deposition in the form of sodium biurate in the tissues. Upon the demonstration of these features the diagnosis of gout should depend. Modern laboratory facilities are now so readily available that an examination of the blood for the amount of uric acid present should be a routine procedure in its absence or in the absence of definite tophaceous deposits the diagnosis of gout will lack proof. Uric acid may be present in the blood in excess in other diseases such as leukaemia but is deposited in the tissues only in gout. Such deposits may not be easy to find and are detected in probably less than a third of the cases. The amount of uric acid in the blood should not exceed 3.5 mg per 100 ccm in women and 3.7 mg in men though these limits may sometimes be exceeded without the appearance of symptoms of gout. In a small proportion of cases of gout the content of uric acid in the blood is within normal limits and when this is the case other evidence will need to be very clear to justify the diagnosis. It is possible that the rate of deposition may vary widely and that in some instances the excess is quickly deposited and the level in the blood kept at or below the normal whereas in others the affinity of the tissues is less pronounced and the excess of uric acid is removed from the circulation more slowly. For long the question has been

debated whether the excess of uric acid is due to increased production or diminished excretion and whether the fault lies with the liver or the kidney. That the kidney is not primarily at fault is clearly shown by the fact of the increase in excretion during an attack. Sir Walter Langdon-Brown supported the view that normally the uric acid reaches the kidney conjugated with a nucleoside and that its retention may be due to the failure of this conjugation to occur. Many years ago Sir Alfred Garrod observed that the amount of uric acid excreted by gouty persons between the attacks fell far below the normal level in many instances. Deposits of sodium biurate have often been demonstrated in the articular cartilages of persons who have never been the subject of acute attacks, and apart from the formation of tophi it is reasonable to assume that deposition takes place in other connective tissues and is the basis of abarticular gout, though further investigation in this direction is required.

The acute paroxysm is not due, it would appear, to the deposition of uric acid but more probably to its reabsorption under the influence of some other factor. The view has been advanced that the tissue cells in whose neighbourhood deposition takes place are thus sensitized, and in the presence of some allied product of purin metabolism an allergic reaction takes place, resulting in the discharge of biurate into the circulation from these deposits with the production of the local inflammation as well as the constitutional symptoms of the acute paroxysm. Such a view, however, does not explain the symptoms and general characters of the more chronic types of gout as seen in these days. That it may assume forms which differ widely from the classical type is coming to be much more recognized and may lead to a revision of the opinion often expressed that the disease is much less common than formerly. Ludwig, Bennett, and Bauer<sup>1</sup> have reported a case which was diagnosed as rheumatoid arthritis in its earlier stages but which showed definite gouty tophi later, with ankylosis of many joints, especially the fingers. The authors make the following important observation: "Many of the so-called specific therapeutic measures for rheumatoid arthritis such as vaccines, sera, colloidal injections, removal of infected foci, colon irrigations, endocrine therapy, etc., are prescribed and erroneously given credit for curing an attack of rheumatoid arthritis, whereas the patient was suffering from a self-limited attack of gouty arthritis." Many physicians of experience in joint diseases will agree with this statement. It is important that these aspects of gout should be

more generally recognized, for gout may imitate very closely rheumatic fever and gonorrhoeal arthritis as well as rheumatoid arthritis. Tophi may easily be overlooked if not searched for, if present they will furnish the most trustworthy clue available to clinical investigation. Examination of the blood will often reveal an unexpectedly high level of uric acid in cases diagnosed as fibrositis and sometimes in what appears to be typical rheumatoid arthritis. Olecranon bursitis should always arouse suspicion, it is due to gout more often than to any other condition. The authors state that the initial attack of gout only affects the big toe in 54 per cent of cases. Even this figure may be found to be too high on further study. The part played by low-grade sepsis appears to be important, and the variability of the sedimentation rate in cases of gout indicates that a septic infection is often a factor in the development of gouty symptoms of the chronic type. On the other hand, an arthritis may be caused by a septic focus in a gouty individual in whom the presence of uratic deposits may play no part in the production of symptoms. It is at least certain that many cases of so-called gouty iritis have been solely the result of septic infection from teeth or tonsils. The only means of differentiation appears to lie in the specific action of colchicum in relieving symptoms of gouty origin.

The discussion at Bath covered a wide field, and the observers from many countries who took part made several valuable observations. Dr van Breemen of Amsterdam ably summed up the position by remarking that we had accumulated many bricks of knowledge but lacked as yet an architect who could construct a building from them.

### SURGICAL TREATMENT OF DIABETES

Although the history of medical research shows a few instances in which experiments based on insecure generalizations have chanced to be brilliantly successful, the vast majority of such experiments have ended in failure. In research this failure harms only the ill-conceived hypothesis, but when surgical procedures on the human patient are undertaken on similar insecure foundations the result may be harm to the patient. This is nowhere better illustrated than in the attempts which have been made to effect a cure of diabetes mellitus by surgical means. As an apt example, removal of the suprarenal glands may be mentioned. In some animals, but not in others, resection of these glands ameliorates pancreatic diabetes, unfortunately it is also true that fatal "Addison's disease" is produced by the same procedure. It is not therefore surprising to learn that resection of varying amounts of suprarenal tissue in human diabetics has had little if any effect upon the diabetic state but has resulted in fatal Addison's disease.

<sup>1</sup> *Ann Intern Med* 1938, 11, 1248

Sendrail Cahuzac and Garipuy<sup>1</sup> have recently recorded observations on dogs which lead them to think that diabetes mellitus may be benefited by periaarterial sympathectomy performed on the pancreatic arteries. As this operation has not yet been applied to diabetic patients criticism of the experimental results may be timely. The investigation was apparently inspired by Lenche who struck by Allen's observation that manual obliteration of the arterial supply to the pancreatic remnant in a partially depancreatized dog resulted in diabetes asked if augmentation of the flow of arterial blood to the pancreatic remnant would not guard the animal against this disorder. The results of periaarterial sympathectomy of the dog's pancreatic arteries are recorded in their paper. After the operation there was first a short period of hyperglycaemia and then a period in which the blood sugar returned almost to normal. For the next two months there was a gradual rise in the fasting blood sugar level and finally a fall of the blood sugar to subnormal levels which persisted until the animals were killed at the end of a year or so. The changes in the glucose and insulin blood sugar tolerance tests reflect these variations in fasting blood sugar. The authors interpret these variations as being due to corresponding variations in the rate of secretion of pancreatic insulin consequent upon changes in the flow of blood through the pancreas. They claim that the subnormal fasting blood sugar levels which finally persist indicate permanently increased secretion of insulin. Many workers however would not consider these blood sugar levels significantly low but would regard them as the usual levels in dogs which have become habituated to a routine of regular meals and restricted exercise. An attempt has been made to correlate these biochemical changes with the appearance of the pancreas. Immediately after the operative manoeuvres the pancreas becomes blanched. During the next month or two it assumes a 'une teinte violacée' which may be so marked that it may be difficult to distinguish the pancreas from the spleen. Parallel with this increasing cyanosis of the pancreas an increase in weight of the organ occurs so that it may become two or three times heavier than normal. The final stage is reached after two or three months when the cyanosis disappears and the weight of the pancreas returns almost to normal values. It is in interpreting the cyanotic colour of the pancreas as indicative of hyperaemia that the authors may perhaps be in error for cyanosis means not increased but retarded blood flow. It appears more reasonable to interpret the cyanotic colour as indicating a considerable degree of passive pancreatic congestion and this interpretation is supported by the accompanying rapid increase in weight of the gland which can most easily be attributed to oedema. A simpler explanation of their results would then appear to be as follows. The operation is followed by the hyperglycaemia which always follows manipulation of the pancreas. With recovery from operative trauma however the pancreatic function returns and the blood sugar falls. During the next two months scar tissue develops and constricts the veins so that the

pancreas becomes congested increases in weight and appears cyanotic the outflow of insulin from the pancreas is consequently limited so that the fasting blood-sugar level slowly rises. Finally a collateral circulation of veins develops circulation through the pancreas again becomes normal and the blood sugar falls to normal levels. So long as this simpler explanation of the experimental results is tenable it would appear unjustifiable to use the conclusions of Sendrail and his colleagues as a guide to operations of a like nature on diabetic patients.

### PREVENTION OF BLINDNESS

The Prevention of Blindness Committee was established by the Union of Counties Association for the Blind to correlate certain parts of the work of the voluntary agencies concerned with the care of the blind. The committee has done good work. It will now cease to exist for the Ministry of Health has agreed to appoint a standing advisory committee on blindness including the prevention thereof which will carry on the work initiated by the voluntary committee. The committee has issued five reports on the causes of blindness. The fourth publication issued in May 1936 was a notable piece of work. A supplement to this report is now issued which embodies an analysis of a preliminary classification of the causes of blindness and which the committee holds indicates further lines of research and also emphasizes the value of certain regulations for the prevention of blindness and the need for increased facilities for remedial treatment. The report shows that the number of registered blind in England and Wales in 1922 was 34,394 and in the last return (for 1936) it had increased to 67,521. The increase it is stated cannot be interpreted as a growth in the incidence of blindness in the country. It is due to increased benefits available for the blind and therefore to better registration. Analyses of the causes of blindness are given for several thousand cases mostly of persons over the age of fifty. The main causes of blindness in order of frequency are: primary cataract 24.97 per cent, glaucoma 11.09 per cent, congenital defects 10.96 per cent, myopia 10.24 per cent, local infections of the eyes of the eye 5.97 per cent, congenital syphilis 5.12 per cent, acquired syphilis 2.83 per cent, ophthalmia neonatorum 4.91 per cent, trauma and disease 1.39 per cent, other categories 22.52 per cent. In the return received from different places there are remarkable variations these need further inquiry and explanation—for example blindness from myopia in Scotland is put as high as 17.1 per cent. and in Birmingham as low as 4.4 per cent whereas for the greater number of cases from England and Wales the proportion is 10.24 per cent. It is of interest to note that no less than 83.85 per cent of those blinded by ophthalmia neonatorum were born before the regulations regarding the prevention of this disease came into effect and only 16.15 per cent were born since 1914 (the year in which the Public Health (Ophthalmia Neonatorum) Regulations came into operation) and none since 1932. The

<sup>1</sup> Report on an Analysis of the Primary Causes of Blindness in Great Britain by the Prevention of Blindness Committee, 1936.

could be no more emphatic endorsement of the value of scientific measures for the prevention of disease than such figures as these. But all causes of blindness are not so amenable to control as is ophthalmia neonatorum. The work initiated by the Prevention of Blindness Committee has been of great value. We may wish a continuity of success to the new advisory committee of the Ministry of Health.

### INDIGESTION AND PATENT MEDICINES

The commercial make-up of the wireless programmes in the United States of America seldom fails to astonish the newcomer to its shores though impatience with the smooth-tongued announcers' dogmatic advice concerning gastro-intestinal misconduct is often tempered by apprehension of the infinite harm such propaganda might do to the more credulous listeners. The gravity of this problem is brought home by A. B. Rivers in an article, "The Dangers of Treating 'Indigestion' by Advertised Nostrums" in the *Proceedings of the Staff Meetings of the Mayo Clinic* for February 9. His recent survey of the incidence of dyspepsia among a large number of patients attending the clinic shows that nearly half between the ages of 30 and 60 include among their complaints that of indigestion. In men over 40 the most frequent causes of this are listed as follows in percentages: peptic ulcer 23, functional 20, cancer of the gastro-intestinal tract, pancreas, etc., 17, cancer of the stomach 12.2, cholecystitis 9, cardiovascular disease 5. In women over 40 the figures are: cholecystitis 24.5, functional 19.8, peptic ulcer 9.5, cancer of the gastro-intestinal tract, etc. 5.8, cardiovascular disease 4.8, cancer of the stomach 4.2 per cent. In studying this table it is startling to think of the fate of dyspeptic men and women over the age of 40 whose symptoms are temporarily masked by patent medicines so that they procrastinate in seeking medical advice. But in all matters relating to disease, Sir William Osler said nearly thirty years ago, credulity remains a permanent fact uninfluenced by civilization or education.

### COORDINATING MEDICAL RESEARCH IN CANADA

Sir Frederick Banting, Director of the Department of Medical Research at the University of Toronto, has been nominated by the National Research Council as chairman of a new committee to study the organization of medical research in Canada. This action was taken on the recommendation of a conference on medical research held in Ottawa and attended by representatives of all the medical schools, organizations, and institutions concerned in medical research, including the provincial departments of health, the Department of Pensions and National Health and the National Research Council. Four *ex officio* officers are the President of the National Research Council, the Deputy Minister of the Department of Pensions and National Health, the President of the Canadian Medical Association and the President of the Royal College of

Physicians and Surgeons of Canada. To complete the personnel of the committee invitations have been extended to twelve distinguished members of the medical profession, each of whom has specialized knowledge in a particular field and all have a broad general training and comprehensive knowledge of Canada's requirements in medical research. In order to provide continuity and adaptability members will be appointed for terms of two, three, or four years, and will be eligible for reappointment for a further term. Dr. T. H. Leggett, who retires from the presidency of the C.M.A. in June, has been asked to serve as an additional special member so that the committee might have the benefit of his wide experience. It has been suggested by many members of the medical profession in Canada that the formation of this committee on medical research under the National Research Council might well be a first step towards the formation of a medical research council for Canada similar to that which exists in Great Britain. The immediate purpose of the committee is defined in the terms of reference, which are: (1) to receive suggestions for requirements in respect of medical research and in matters related thereto; (2) to consider by whom the investigations required can best be carried out and to make proposals accordingly; (3) to correlate the information when secured and to make it available to those concerned; (4) to do such other things as the committee may deem advisable to promote medical research in Canada. The conference agreed that the scope of the new committee's activities should not be limited to particular subjects, but that it should be empowered to investigate the whole field of medical research in Canada. One of the first steps to be taken will be to make a survey of the work in progress at various centres to determine how the activities of the institutions concerned may be developed to the best possible advantage.

### THE MACHINE AND THE WORKER

In Report No. 82 of the Industrial Health Research Board,<sup>1</sup> Messrs. S. Wyatt and J. N. Langdon, assisted by F. G. L. Stock, describe their investigations on women employed upon various kinds of machine-feeding processes. Such work is pursued, year in and year out, by hundreds of thousands of persons, and its extent is likely to increase in the future as the mechanization of industrial processes develops. The work is inevitably monotonous, so it is of outstanding importance that the degree of monotony should be reduced, where possible, by choosing the most favourable conditions of work. It is only by careful and exact measurements such as are described in this report that the requisite information can be ascertained, and several conclusions of direct practical value have already been arrived at. The authors point out that the outstanding psychological problem is the conflict between mechanical uniformity on the one hand and human capacity on the other. The management tend to run their machines at the highest possible speed in the hope of increasing output but in consequence of this many

<sup>1</sup> H.M. Stationery Office (9d)

operatives find themselves struggling to work it a pace which they are unable to maintain and fall victims to strain and over fatigue. In some instances it was found that a slowing of machine speed improved the output substantially but on the other hand some of the machines were run at too slow a pace and their acceleration was welcomed by the operatives. The most suitable speed naturally varies a good deal in different individuals and it also varies in the same individual at different times of the day according to her state of alertness or fatigue. The most satisfactory method of overcoming these variable requirements is to fit cone pulleys to the machines whereby the operator can at any time change the speed to what she thinks to be best suited to her immediate desires. As the operators are on piece rates there is no likelihood that they will work at too slow a rate. The personal likes and dislikes of the workers were probed by means of questionnaires and the replies were very instructive. The most popular likes of the operatives employed on machine feeding were pleasant working companions, hours of work not too long and good wages while the most frequent dislikes were aroused when the operatives had to wait at the machines for the arrival of material. The adverse effects of noise, monotony and fatigue were not referred to nearly so frequently. Nearly two hundred women employed on belt-conveyors were interrogated. This type of work is less popular than machine feeding and the operatives were much more subject to monotony. This was owing to the simplicity and uniformity of the movements performed and the restraining influence of the conveyor which moved at a uniform rate with very few stoppages from mechanical or material cause.

### SMOKING AND LONGEVITY

Professor Raymond Pearl of Baltimore has not always or even usually been a writer grateful to those who desire to control the amusements of their fellow creatures. The family history records of his laboratory gave a testimonial to the moderate drinker and perhaps members of the anti tobacco league (if there is such a body) or our esteemed colleague Dr J D Rolleston may not have expected much support from the Department of Biology at Johns Hopkins. But eleven years ago Dr J Rosslyn Earp<sup>1</sup> working in the department showed statistical reason for thinking that at least at one college students who smoked did not do so well either in work or play as abstainers. Now Professor Pearl gives life tables from age 30 for 2 094 non-users of tobacco, 2 814 men who smoked tobacco in moderation but did not chew or use snuff and 1 905 men who were heavy smokers but did not chew or take snuff. The non smokers have the advantage slightly over the moderate and greatly over the heavy smokers. Thus 45.9 per cent of the non smokers (it must be remembered that the age of entry is 30 years) live to 70, 41.4 per cent of the moderate smokers but only 30.4 per cent of the heavy smokers. In this sizable material

the smoking of tobacco was statistically associated with an impairment of life duration and the amount or degree of this impairment increased as the habitual amount of smoking increased. This is a preliminary communication and naturally Professor Pearl refrains from drawing aetiological conclusions. He states a correlation but some little distance must be travelled before one can be sure that non smokers live longer than smokers because they do not smoke. However as the financial interests of those who sell tobacco are on the same order of magnitude as those of the vendors of alcoholic drinks and the pipe has inspired almost as much prose and verse as the wine can force words whether had tobacco been in use in the Rome of Augustus, Horace would have surpassed Odes III 21: we may safely predict a lively controversy.

### CHEMOTHERAPY IN VIRUS DISEASES

It has recently been reported by Rosenthal, Woolley and Bauer<sup>1</sup> that prontosil exerts a protective action against lymphocytic chorio meningitis in mice. This observation denotes an entry into the wide field of virus diseases where there was no previous reason for supposing that these drugs would have any effect since viruses differ profoundly from bacteria in many ways including their reaction to destructive chemical agents. There is still no evidence that prontosil or sulphanilamide will influence the course of any virus infection in man unless in the form of reports that the latter will abort colds and since colds may sometimes be due to bacteria such evidence is inconclusive. There is now however another arresting report of successful chemotherapy of virus disease in an animal. Sodium sulphanilic sulphanilate a compound chemically related to sulphanilamide is said by A R Dochez and C A Slanetz<sup>2</sup> to have not only a prophylactic but a well-marked therapeutic effect in canine distemper. This distinction is profoundly important: the intracellular position of the virus in established infection might well be regarded as making it inaccessible to chemotherapeutic agents just as it is to specific antibodies. The contrast between the efficacy of serum in protecting against virus infections and its uselessness in treating them is complete and well known. The authors of this short paper do not discuss this aspect of the matter nor do they discuss the chemical relations of the drug used or disclose the process of reasoning or experiment which led to its choice. Their findings in experimental distemper are supported by the results of treating twenty-eight cases of the spontaneous disease of which twenty-six recovered. The treatment was also found effective in cat distemper. In view of Dochez's almost lifelong interest in virus diseases of the respiratory tract it may be presumed that he will have no opportunity of trying this treatment in influenza.

The King and Queen will pay an official visit to Birmingham on Thursday July 14 to open the new Hospitals Centre.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## TREATMENT OF FACIAL WOUNDS AND CUT THROAT

BY

JULIAN TAYLOR, M.S., F.R.C.S.

The management of accidental and operative wounds of the face is an attractive task, since as a rule their healing leaves final appearances so pleasing that our patient's satisfaction is often commensurate with our estimated deserts. The normal sound healing of the face and the inconspicuous surgically beautiful scars that are easily attained may be ascribed in some measure to two causes—the abundant supply of blood to the facial tissues and the perpetual exposure of its skin to the beneficial effects of air and sunlight. With wounds elsewhere, in ambulant patients, these latter influences are difficult to maintain as adjuvants to healing, since most of the rest of the body is habitually swathed in clothing that insulates it as effectively as does a surgical dressing. The hands, it is true, are bare, but they are in too constant use and movement to permit us to dispense with protective dressings and even splints, in any but the most trivial wounds. The scalp is in striking contrast with the face in surgical behaviour, for though nowhere is surgical skill more certainly rewarded, the neglected scalp wound may become dangerously and heavily infected unless the hair has been shed, when the chance of healing by first intention approximates to that enjoyed by the face. The hairy scalp, however, is handicapped by the habitual presence of dirt and desquamations, for whereas everybody's face is commonly kept clean, in all classes and in both sexes the condition of the scalp is hardly what Western culture might lead us to expect. Furthermore, once healing has occurred in the head and neck, the later conversion of young and vascular cicatricial tissue into a linear contracted and inconspicuous scar is a much more speedy process than in most other parts of the body. This is partly on account of the influences noted and partly because in the erect or seated attitude those portions are the highest in the body and are thus immune from the effects of venous congestion, which may long delay the whitening of scars of the extremities and lower abdomen and may also be among the causes of stretching of scars in the latter positions. The head and neck being thus favourable for success, it remains for us to concentrate our attention on the methods of securing first-intention healing and narrow linear mobile scars.

### Abrasions

If there is visible dirt in an abrasion it should be gently removed with forceps or mops and anti-tetanic serum given in most cases. Should bleeding be still proceeding it may be checked by light pressure with a mop wet with normal saline water, or a mild antiseptic, and when it has ceased the abraded surface may be left to ooze. The exudate is the best antiseptic, and the scab produced by its clotting is the natural and by far the best dressing. Abrasions so treated heal well and the scab should be left in place until it drops off in days or weeks, according to the depth of the abrasion, when supple skin overlying a minimum of scar tissue is seen to have been formed under it. There

is no need to disfigure the face even temporarily with coloured and irritant antiseptics like flavine, iodine, and picric acid, it should be remembered that any of them may produce a chemical inflammation of the skin, a dermatitis that occasionally may outlast the healing of the wound and even spread from the site of application. Tannic acid is a better application than any of those named, but it is unnecessary, and its blackened ugly coagulum is no improvement on a wholly natural scab. If an antiseptic is desired in the case of a dirty or greasy skin, industrial spirit is as good as any and its effects are fleeting.

In advocating the use of the natural dressing of blood clot we may go further and say that any kind of cotton or gauze covering is prejudicial, partly because it may result in mild suppuration that would not have occurred without it and partly because its removal may result in trauma to the healing tissues, so that a corresponding excessive formation of scar tissue results. Only or greasy applications are still worse, and it may be said in strict truth that the surest and almost the only way to make the face suppurate is by applying some form of dressing, indeed, one may go still further in stating the claims of unimpeded Nature, for when, as often happens, a two- or three day old abrasion is already beginning to suppurate owing to the employment of a mistaken form of treatment, the surest way to check the process is to remove all dressings, ointments, etc., and allow the exuding pus to dry, while to continue their use is very likely to result in the development of an infective and resistant dermatitis.

### Incised Wounds

Where the skin is ruptured the final appearance of the resulting scar depends partly upon the success with which accurate apposition of the cut skin edges has been achieved, partly upon to what degree the underlying facial musculature, closely attached to the deep surface of the dermis, has, if divided, been prevented from retracting and partly upon the attention paid to the niceties of skin suture. The permanent marks of stitches, even where a narrow linear scar has been made, cannot fail to draw attention to what otherwise might have been so inconspicuous as to be almost invisible. Stitches make permanent marks more by slight sloughing of the included skin than by the punctured wounds of needles, which nevertheless, if not very small, do remain visible. It therefore behoves us to use small sharp needles, but these are of no avail if we fail to employ fine and flexible suture material, if we tie our stitches too tightly, or if we leave them in place too long. It is obvious that some of the most perfect facial scars are attained by the methods evolved by plastic surgeons, among these is the use of fine buried catgut for facial muscles, with fine stitches for closing the skin, which are removed after a day or two, the buried catgut then holding the wound closed while the healing of the skin proceeds. Such methods, however, entail not only the possession of special skill in burying catgut sutures aseptically but also of suitable material against an emergency, and thus we prefer to describe simpler ways that are effective and also available for the general practitioner who has not at hand the conveniences of the operating theatre.

### Suture Material

This should be flexible and fine. Silk is finer than linen thread of a similar strength, and is thus preferable but both have the disadvantage of needing prolonged boiling to achieve sterility. Horsehair may be brittle and thus unhandy. Gossamer or ophthalmic silkworm gut natural or synthetic is one of the pleasantest materials in use being strong for its bulk, flexible in adjustment of tension and painless in removal though the natural gut is hard to obtain just now owing to the war in Spain. The worst suture material is probably the ordinary medium or coarse silkworm gut that is found in so many theatres. It is stiff its tension cannot be accurately judged or applied it causes sloughing of the stitch track because even when correctly applied it does not adjust itself to the contents of its loop and its rigidity makes it painful on removal. Indeed the need for the use of a fishing gut with a tensile strength of half a hundredweight is not obvious in any part of the body.

### Instruments

It is well to have fine toothed dissecting forceps and fine pointed artery forceps such as are used for venesection. Needles should be the slimmest triangular pointed ones that will admit sutures or better still the practitioner who likes to be well equipped may keep some of the tubes of atraumatic skin sutures that are prepared for plastic skin surgery and that are employed by Sir Harold Gillies. For use with a holder needles should be curved in the hand small sizes are more convenient if straight.

### Closure of Incised Wounds

Facial wounds that gape at all are better closed by suture unless they pass so obliquely through the skin as to make suture impracticable when the thin flap of skin may be kept in place by pressure maintained by a single layer of open-weave gauze stuck to the skin by means of mastic varnish (for example benzo-mastiche Martindale) but care must be taken to use only one layer of gauze and a minimum of adhesive. A straight incised wound in a patient with self-control may be closed without an anaesthetic but where there is any technical difficulty the practitioner is advised to content himself with the arrest of bleeding and a temporary dressing until an anaesthetic be available though novocain injected round the wound may be all that is necessary. He should remember that although it is a good general rule to deal with compound injuries without delay the exceptional healing capacity of the face gives him a little latitude in action that the final result must be as near perfection as possible and that such an end can be achieved only by an unhurried deliberate and accurate operation. In preparation the mechanical removal of dirt from the skin and the depths of the wound and perhaps the cleaning of the skin with spirit are the only things necessary.

Bleeding is best stopped by pressure maintained for five minutes or so but if it is obstinate spurting vessels may be caught with artery forceps and subsequently either ligated or better still included in the bites of sutures unnecessary buried material in a field of doubtful cleanliness being thus avoided. It should be remembered that novocain is a vasoconstrictor and with the passing of its effect's bleeding may recur under the closed skin. The cut skin edges must be clearly seen and the obliquity of the cut to the surface estimated. As many deep stitches as may be necessary to hold the facial muscles together are inserted through the skin preferably as small mattress

sutures protected by bits of fine rubber tubing but if this last is not available stitches embracing muscles and skin are quite satisfactory provided they are effective and are not tied so tightly as to cause sloughing of underlying skin either immediately or with the onset of the slight inevitable swelling of early healing. Small stitches taking skin only and very close to the cut edge are then inserted so as to approximate the edges of the wound accurately their positions and individual tensions being most easily judged if all superficial and deep sutures are inserted before tying the knots. This is the method that was most commonly employed in the days when carcinoma of the tongue was frequently excised after splitting the cheek and the resulting facial scars of many of them are so perfect that one has to examine them with a magnifying glass to ascertain their presence or extent.

### Removal of Stitches

It is probably unwise to remove stitches holding muscle together at a shorter period than four days but where they are holding only skin they may be safely removed after two days though it is better for the surgeon's peace of mind if on so precocious a removal the wound be held together with a single layer of loose woven gauze and mastic varnish clear of the actual cut as earlier described. Such a dressing does not prevent air drying of the slight exudate that may still come from the wound and stitch holes and though not ideal it is better than leaving *in situ* stitches whose marks the passage of time may make indelible.

### Lacerated and Contused Wounds

Contusion of course causes some swelling but remembering the great capacity for healing that the face possesses we need not hesitate to close a laceration on account of accompanying swelling and ecchymosis. Maximal swelling from contusion occurs in the eyelids and it should be remembered that a wound of the forehead penetrating the frontal sinus causes a subcranial effusion of blood that passes without encountering obstruction into the upper eyelids which may rapidly swell and close the palpebral fissure completely. An early effusion into the upper eyelids only need the forehead area of no suspicion of fractured skull. Lacerated wounds should also be closed according to the same rules as those described earlier and only with the greatest reluctance should skin be excised because it is damaged if an excision be necessary it should be minimal and if possible be limited to the extreme devitalized edge. Where skin has been torn away and lost an immediate Thiersch graft is advisable but if it be in any wise possible to replace an actual detached piece this is the best graft. After suture of facial wounds the process of shrinkage of the cicatrix proceeds rapidly and in small wounds is complete in about a month by which time the scar will have attained its final pale appearance. With larger wounds and lacerated ones or if by any chance there has been suppurative the duration of the final shrinkage and devascularization is much longer and may last six months or more depending upon the intensity of the cicatricial reaction. In these cases it is only at the lapse of such a period that it is possible to judge as to the advisability of secondary excision of a disfiguring scar. A satisfactory facial scar is one which is linear, pale and almost invisible. It is flush with the surrounding skin and neither dimples nor distorts the face with expressional and other movements. The elements that go to make up disfigurement are those of scarring from sloughing, inflammation and inaccurate approximation of

the skin edges, loss of substance resulting in deformities, especially of the eyelids, dimpling, with adhesions of scars to deeper structures due to unsuccessful closure of the facial muscles, partial paralysis of muscles due to section of filaments of the facial nerve, and occasionally swelling due to lymphatic obstruction—the last being seen sometimes in the lips, and also where the nose has been almost detached from its root so that the end becomes bulbous from lymph stasis, a condition fortunately tending to disappear spontaneously

#### Wounds involving the Nares and Lips

In these wounds the test of success is the accurate approximation of the edge of the nostril or of the red margin of the lip. In the nostril this is easy, but where there is laceration the red margin may be difficult to see. It is usually possible to impale a healthy part of the red margin with a small pin on each side of the wound and thus to judge the correct placing of the sutures. If the lip be cut right through into the mouth the mucosa must be closed with catgut before approximating the skin, and owing to the thickness of the muscle of the lip it is usually advisable in this situation to use buried catgut also to close the muscular wound. In the lips and nostrils, where there necessarily is continual wetting of the wound, it is of especial importance to eschew all dressings and to leave the sutured wound uncovered. To keep such wounds partially covered with mucus- or saliva-soaked dressings is to ask for them to be infected, a request that in such circumstances is only too often granted.

#### Wounds of the Face with Compound Fracture

What has been said of closure of facial wounds applies to all, whether associated with fracture or not. Where a fracture is suspected an x-ray examination should be arranged at once, and if, as will usually be the case with a positive result, it is decided to call in surgical assistance it is better to do so as an emergency than to close the facial wound and then arrange a consultation at leisure. The alveolar margins and jaws, the malar and nasal bones, and the region of the frontal sinus are the common sites of fracture. Of these, it is true the jaws can, if necessary, usually wait a day or two for dental treatment without prejudice to the final result, but the nasal and malar bones are often depressed and need elevating, which should be done before suturing the facial wound, and the injuries of the frontal sinus carry with them the real danger of associated injury to the cranial contents, of cerebrospinal rhinorrhoea, and meningitis. The surgeon confronted with a sutured wound over the frontal sinus a day or two after its infliction may find himself in great difficulty, being uncertain how to proceed with the possibility of an already established frontal sinusitis and a possibly open cranial cavity.

#### Wounds of the Neck and Cut Throat

Wounds of the neck should be treated on the lines indicated for the face. Skin stitches that include the platysma, properly applied without excessive tension, give narrow scars that are almost invisible.

Suicidal cut throat is the result of a wound usually made with the right hand, and is thus more extensive on the left side than on the right. The vigour of the suicide is apt to be spent in the length of his incision rather than its depth, and the level chosen is often that of the thyrohyoid membrane, presumably because the thyroid cartilage can easily be felt as an obviously resistant structure under the skin. Less often the wound is made above

the hyoid bone, and rarely it is below the cricoid cartilage. In half-hearted attempts such wounds may be superficial only, but often they penetrate the air passages, in the common subhyoid variety opening the supraglottic part of the larynx, while in the less common suprahyoid wound the vallecula is penetrated, in either case the epiglottis often suffers partial or complete separation. In the subcricoid variety the trachea may be opened. These are the injuries actually inflicted as a rule, though the object of the suicide is presumably to open a large blood vessel in the neck. In the first two varieties, owing to the backward passage of the carotid sheath as it ascends the neck, its contents are in little danger, nor are the superior thyroid, lingual, and external maxillary vessels, though these are nearer the site of injury. Actually the large vessel damaged most frequently, in my experience, is the common facial vein, from which it is possible for a patient to become almost exsanguinated, but in a low wound the thyroid gland and the jugular vein may be involved. Nevertheless the brunt of the injury usually falls on the respiratory passages rather than on the vessels, at any rate in the cases arriving in hospital. An example of this occurred during the great war, when a soldier at the end of his endurance cut his throat one evening and reported sick in the morning holding a towel to his neck. He had divided his epiglottis and had incised his posterior pharyngeal wall, but there was not a great deal of bleeding.

When the thyrohyoid membrane is cut the gash does not open widely, but in suprahyoid wounds the suspension of the larynx is partly lost, so that the wound gapes and the interior of the oropharynx can easily be inspected. Whichever level is chosen for cutting there is danger of asphyxiation from blood or loose fragments of epiglottis and laryngeal mucosa entering and obstructing the airway.

#### TREATMENT

With a closed respiratory passage the superficial wound is treated by ligation of whatever vessels may be necessary and by closure of the wound as described for other neck wounds. It is usually well to drain the deepest part, and this as a rule is in the middle line. With an open pharynx or larynx an anaesthetic is necessary, and when respiration is obstructed preliminary tracheotomy should be performed without hesitation. The upper opening can then be packed with a cocaineized plug and the wound closed deliberately. The first step is the inspection of the interior of the pharynx or larynx and the removal of any loose fragments likely to cause suppuration or obstruct the airway. The epiglottis may be sutured, or if it is so badly lacerated that healing seems unlikely it may be removed with no fear of deglutition difficulty other than a temporary one. Swallowing, indeed, is impossible in any case in the early days after pharyngeal suture, and before closing the wound a catheter must be passed into the oesophagus and brought out through the mouth, where it is fixed by a suture through the cheek or a loop round the auricle. The pharyngeal mucosa is then closed with catgut, but the skin is left widely open except where there is no underlying pharyngeal wound. Closure of the skin carries with it a danger of infection of the fascial planes of the neck from the opened pharynx. If a tracheotomy tube has been used it may with advantage be left in place for a few days until it is certain that there is not enough inflammatory swelling of the upper opening of the larynx to obstruct respiration. A damaged trachea may be closed if not lacerated, after adequate exposure of the operative field, preferably under local analgesia with cocaineization of the tracheal mucosa. It

the condition of the trachea be thought unsuitable for suture a tracheotomy tube should be inserted for a few days the wound being left open and packed with a small plug round the tracheal opening. This will suffice to prevent infection tracking in the fascial planes to the mediastinum and the plug may be removed when a layer of protective granulations is well established. In no circumstances should a sutured trachea be covered by a closed skin wound as not only distressing surgical emphysema but also widespread infection of the neck is the likely consequence.

#### RESULTS

Pharyngeal and tracheal wounds usually suppurate for a time, especially if there has been loss of blood; this if severe may be replaced by transfusion should it be thought advisable to take healthy blood to revivify a suicide. Often a temporary pharyngeal fistula occurs but such openings eventually heal of their own accord in most cases. If healing fails a small plastic closure is easily effected when the fistulous track is completely covered with epithelium.

## TREATMENT OF SYPHILIS

### A SURVEY OF CURRENT METHODS

W. R. Snodgrass and R. J. Peters<sup>1</sup> under the auspices of the Medical Research Council have undertaken a survey of the results of treatment of early latent and mucocutaneous tertiary syphilis. Their report shows not only how these forms of syphilis should be treated but also what results may be expected from treatment—adequate or inadequate—begun in the various stages of the disease. Early syphilis can usually be treated according to a set plan of standard courses each of which should consist of not less than 5 grammes of 914 and about 2 to 2.6 grammes of bismuth metal the whole being given over a period not exceeding fifteen weeks. Treatment is most effective when given early regularly and adequately. Clinical relapse was noted in only 2.8 per cent of the adequately treated cases as against 8 per cent of the inadequately treated. It is the first course which is important for of the cases receiving total adequate treatment those who had had an adequate first course showed a much lower relapse rate than those whose first course had been inadequate. In general for early syphilis one standard course after the Wassermann reaction has become negative represents optimum treatment. An intensive first course gives the best results and the intervals between courses should be reduced to a minimum. It is claimed that the author's intermittent concurrent use of 914 and bismuth gives at least as good results as the continuous alternating method recommended by the American Co-operative Clinical Group. Examination of the cerebrospinal fluid would seem to be unnecessary in the absence of symptoms referable to the central nervous system appearing before the end of the second year.

Intolerance is one of the bugbears of antisyphilitic therapy and a frequent cause of defaulting and inadequate treatment. Specific measures for avoiding it are lacking but care in the preparation of the patient especially the detection and elimination of focal sepsis and in the technique of injection will reduce its incidence. Jaundice occurred in twenty-three cases (4 per cent) in the series in twenty-two of these during the first course but in only three was it severe, one patient died of acute yellow atrophy of the liver. Only thirty-six of 7300 injections

(0.49 per cent) provided skin reactions which in six cases amounted to dermatitis. Though it often lessens the total amount of treatment intolerance often coincides with maximum therapeutic results. Thus 11.4 per cent of unfavourable final results were recorded in cases having intolerance as against 19.7 per cent in cases not showing intolerance out of a total of 570 cases.

### Latent and Tertiary Syphilis

Latent syphilis is defined as syphilis of more than 2 years duration with no clinical signs but showing a positive blood reaction. The question arises as to whether such a case should be treated. The answer is that it should because treatment lessens the incidence of late syphilitic lesions, may prevent conjugal infection by means of the spermatic fluid and prevents hereditary syphilis. Of the cases under review treated and observed for more than two years clinical and serological tests were negative in 50 per cent at the end of that time in contrast to 27.9 per cent in Brunsgaard's series of untreated cases (*Arch. Derm. Syph.* Wien 137, 1909). The former figure agrees fairly closely with that of the combined American clinics. The treatment of latent syphilis is much more unsatisfactory than that of early syphilis though the earlier the case comes under treatment the better the outlook. In general three standard courses were considered sufficient for cases of latent syphilis though in the case of a patient under 40 whose blood test is still positive after two years it is worth while continuing treatment even further since this series showed 5 per cent of clinical relapses after the two years treatment and observation.

Tertiary mucocutaneous syphilis like the latent form responds better the earlier it is treated. Visible lesions heal rapidly and in few cases is there progression to cardiovascular syphilis or neurosyphilis. Clinical relapse was seen in only 2.1 per cent of this series—that is it was practically unknown when adequate initial treatment was given—but intolerance is more common than in early syphilis (4.4 per cent as against 27.7 per cent) and rises with the age of the patient. This and the fact that two years treatment and observation only produce negative Wassermann reactions in 37.2 per cent of patients suggest that it is not usually wise to give long and intensive treatment unless the patient is young and healthy. In such cases many think it is an advantage to employ a quantitative serum test—such as the Sigma<sup>2</sup>—which records results in units—and provided the patient stands treatment well, persevere so long as the blood reaction continues to fall. Generally speaking it was found that two courses of 914 (11.7 grammes) and thirty injections of bismuth (7 to 8 grammes) or potassium iodide orally afforded a very considerable means of protection against clinical or serological relapse. It is doubtful if one can speak of "cure" or any form of late syphilis even if treatment reduces the blood reaction to negative and the patient is clinically free from symptoms; he or she ought to be kept under observation indefinitely. Syphilis of the heart and blood vessels and of the nervous system have not been considered since in the series under review too few cases were observed to warrant analysis.

### Treatment of Early Syphilis

Finally Snodgrass and Peters offer some suggestions on the treatment of early syphilis. The rule of thumb logical relapse is the best single criterion of the value of a drug if only because its incidence is nearly four times as great as that of clinical relapse. Reasoning in this way it is much needed and the question of defaulting becomes large for obvious the more the cases default the more will be the end results. Bismuth and 914 appear to be the drugs of choice and much depends on an adequate first course. It is therefore well worth while making the first course as intensive as possible. In the first 10 to 15 days

<sup>1</sup> Snodgrass W. R. and Peters R. J. *An Analysis of the Results of Treatment of Early Latent and Mucocutaneous Tertiary Syphilis*. Medical Research Council Special Report Series No. 22. Price 2s net. London His Majesty's Stationery Office 1937.

days of the scheme outlined by the two authors 555 grammes of '914' and 26 grammes of bismuth may be given, the first six injections of each being administered twice weekly. Then one month's rest is followed by eight weekly injections of calomel cream with potassium iodide orally. After a further month's rest the combined course is repeated, and then six weeks' rest is followed by ten weekly injections of calomel cream, potassium iodide being taken again orally. After this, two months' rest is allowed before a third combined course. One more combined course should be given after the blood Wassermann has become negative. Thereafter observation, repeated serological tests, and short courses of bismuth or mercury are continued until the end of the second year, when the cerebrospinal fluid should be examined.

Why the authors recommend such treatment is not clear, especially in view of the pronouncements of the League of Nations' experts, who laid down two tried methods—one the "intermittent" and the other the "continuous." If the League of Nations' "intermittent" method was adopted generally it would secure continuity of treatment for those patients who travel about. The scheme suggested by Snodgrass and Peters is open to criticism on the grounds that it has not yet been tried, that the intervals between courses of arsenic and bismuth are prolonged, and that possibly patients might not tolerate well ten or twelve weekly injections of calomel cream, admittedly a somewhat painful remedy. Now that there is in existence a really authoritative statement as to what is the best way to treat early syphilis, it seems a pity to confuse the issue by suggesting a totally different plan, however good it may eventually turn out to be.

## Nova et Vetera

JOHN SHAW BILLINGS, 1838-1913

Bibliographer and Librarian

A quarter of a century has passed since Billings's death, and the echo of eulogy has scarcely died away. Many of those whose tributes were at the time so moving and so eloquent have followed him into the silence. Meanwhile a century has gone full circle, and once again the huge overpowering figure of John Shaw Billings rises before us. To a new generation his features are those of a stranger, and his claims on its remembrance and gratitude must hence be stated afresh. In his life he played many parts and played them well. As virtual creator of the Library of the Surgeon-General of the United States Army he fails to impress the medical student's imagination in this country, so misleading is the official title of the foremost medical library in the world.

### Monumental Achievements

After the Civil War Billings in 1864 was transferred to the Surgeon-General's Office in the War Department, where he remained for thirty years. From a negligible nucleus—in 1865 there were about 1,800 volumes—he built the great library as we know it to-day. By 1880 he had collected 50,000 volumes and 60,000 pamphlets, and in 1895, when he retired, there were over 300,000 volumes and pamphlets and more than 4,000 portraits. In the early days he had no trained assistants, having to rely on hospital orderlies who had served in the Civil War. The work they accomplished is a tribute to Billings's organizing talent. To appreciate the development of his conception of the library as not only a vast storehouse of knowledge but as a dynamic instrument of precision for increasing knowledge and for aiding research we must go back to his student days. For the doctorate at the

Medical College of Ohio at Cincinnati a thesis was required. Billings took as his subject "The Surgical Treatment of Epilepsy." The twenty-two year old student was impressed by the lack of an efficient medical library in North America and of a reliable and comprehensive index to the medical literature. What others might have accepted with regret and resignation Billings translated into a vision of the future, where by sheer force of personality he made it come to life. His thesis, then, was responsible for those monumental bibliographic achievements, the *Index Catalogue of the Library of the Surgeon-General's Office* and the monthly *Index Medicus*. With the former he was in a way lucky, for its publication was financed by the Government, and it is now in its fourth series but the latter had to pass through troubled waters before it became finally merged in 1927 with the *Quarterly Cumulative Index Medicus* of the American Medical Association. The story of the Army Medical Library (before 1922 called the Library of the Surgeon-General's Office) has recently been told by Major E. E. Hume in the *Johns Hopkins Alumni Magazine*, January, 1936, 24, 107-35, and by Colonel H. W. Jones in *Hospitals*, January, 1937, 11, 14-21. The development of the library and its catalogue to Professor William H. Welch was America's most important contribution to medicine, and their father he described as the wisest man he had ever known.

### A Versatile Character

One of the most versatile men of his generation, Billings was librarian, bibliographer, administrator, historian and authority on public health. At one time there was scarcely a hospital of importance in the United States on the construction or rebuilding of which his advice was not sought or accepted. He helped to design the Johns Hopkins Hospital at Baltimore, and suggested the appointment of Osler, Welch, and Halsted to its staff. Retiring at his own request from the Army Medical Library at the age of 57, he became first director of the New York Public Library.

Big both in mind and body, Billings came of Scandinavian stock, and the blood of the Norse Viking fighters was in his veins. That a man of his strength of will and emphatic confidence in his own counsel antagonized those who did not penetrate below the austere surface of the dictator is natural, but at the same time his exuberantly masculine personality made a host of friends by unexpected acts of simple kindness, by his fairness, and his sincerity. As he grew older he became perhaps more mellow and kinder in manner without sacrificing ounce of his virility. His capacity for work was unbelievable, and he attended to the duties of the day with military promptness, seizing upon the essentials. His memory Weir Mitchell compared with the index of a vast mental library. Impatient with verbosity and pretence, Billings's style was clear, precise, forcible, and full of grim humour. Recreation he obtained simply by turning from one form of brain work to another. Books were his true and constant friends. The modern English authors he knew and liked, while his favourite reading was Job, Faust, and Shakespeare. Suffering terribly from insomnia—in his last twenty years he underwent eight operations for cancer of the lip and for calculus—he as a rule read one or two novels at night as 'the best of soporifics.'

Billings has set a standard in medical librarianship which makes the medically qualified librarian play an indispensable part in medicine's daily work. On the occasion of his hundredth birthday—April 12, 1938—it is a matter for regret to find that in this country at least, which is the proud guardian of some of the finest medical libraries in the world, his ideal, both financially and intellectually, remains yet to be captured.

W R B

## THE SION COLLEGE LIBRARY OF MEDICAL BOOKS

The president and governors of Sion College London have decided to sell a large section of the library under their control in order to have funds for the preservation of other sections which they wish to retain. In making their selection for this discard they naturally pick out those books which appear to be and to have been of least use to the Fellows and Members and thus it happens that a very large collection of rare books on medicine and surgery is being sold by auction on behalf of the College on April 21 at Messrs Hodgsons in Chancery Lane. Many of these books were left to the College in two bequests. Dr John Lawson bequeathed a library in 1705 and Archdeacon Edward Waple another in 1712. Lawson was President of the Royal College of Physicians in 1694 and an eminent practitioner in London; he was a friend of Archbishop Tenison on whose account he desired to benefit Sion College. Owing to disuse many of the bindings have deteriorated and most of the covers are broken; the folio volumes have also suffered water stains caused during an overflow of the Thames long ago. Otherwise they are in good condition. Many of the books though old and rather uncommon are not of the superlative age or rarity that means fancy figures in the sale room; it is possible here to particularize only a select few out of the many hundreds that are catalogued for disposal.

### Some Rarities

First must be mentioned a copy of the extremely rare first edition of Harvey's *Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus* Frankfurt 1628 lacking (as many of the extant copies lack) the errata leaf and the blank leaf which constitute signature K—proof that the errata leaf has not been torn out but that this copy was of an early printing and there is also a first edition of the same author's *De Generatione Animalium* 1651. Another great rarity is Dr Thomas Bonham's *The Chyrurgian's Closet* 1630. Furnished with varietie and choyce of Apophlegms Balmes Baths Caps Denufrices Gargarismes Pils Quilts Synapismes Trochiscas for the help and ease of young Practitioners in the Noble Science of Chyrurgerie. Just before this in the catalogue is E Roesslin's *The Birth of Man Kinde* edited by T Raynald 1626 the first illustrated treatise on midwifery in English. Even rarer is Alexander Read's *Treaise of all the Muscles of the whole Bodie* 1637 possibly the only copy in existence. Glisson's *Treaise of the Rickets* (translation) 1651 is the first edition in English of that medical classic.

Of the ancient masters there are seven editions of Galen—1538 1625 1537 1546 1530 1544 and 1586 two of Paulus Aegineta—1538, 1556 one of John Gaddesden—1516 and five of Hippocrates. Alexis of Piedmont is represented by an edition of 1568 and Andrew Boorde's *Breviary of Health* by one of 1552. Another interesting book is a second edition (1580) of Monardes's *Joyfull News out of the Newfound World* wherein are declared the rare vertues of divers Herbs Trees Oyls Plants and Stones (of the West Indies). Englished by John Frampton. In this book the curious will find an account of the properties of tobacco the medicinal uses of iron and a suggestion of the use of snow for preserving perishable commodities by a species of refrigeration.

Sydenham Willis Bartholin Vicary Lettsom Hunter Boerhaave, Mead Smellie Bell Cooper Bright are familiar names which catch the eye further on and there are a few items dealing with the early history of the London Hospital St Georges Hospital the Royal Infirmary, Edinburgh and the Bath Hospital.

## INTERNATIONAL CONFERENCE ON RHEUMATIC DISEASES

### FOUR DAY MEETING AT BATH

The International Conference on Rheumatic Diseases which was held at Bath from March 31 to April 3 was attended by members from thirteen European countries, the United States, Canada and Egypt. It followed immediately upon the International Congress on Rheumatism and Hydrology at Oxford and was held in connexion with the bicentenary of the Bath Royal National Hospital, formerly known as the Mineral Water Hospital. Bath once again shewed upon its visitors its usual hospitality and the civic reception by the Mayor at the Pump Room and the banquet given at the Guildhall also brought in the City were noteworthy events even in a place accustomed to generous and dignified entertainments.

### The Empire Rheumatism Council

Lord HORDER, who was President of the Conference delivered a brief address on the evening of assembly. He said that 1938 was a distinct year in the history of rheumatism because it marked the centenary of the Bath Hospital the holding of the recent congress at Oxford and the establishment of the Empire Rheumatism Council. Throughout his medical life said Lord Horder he had always kept the problems of rheumatic disease in the front of his mind and had come to the conviction that there should be a methodical investigation in order, possible factor connected with causation and treatment. Now they had an organization fitted to carry out such investigation. It had already become active and had set up three research units and had made considerable progress in the matter of systematizing and extending therapeutic treatment. He felt that in the future his work would bring about a notable diminution in rheumatic disease and its foundation prove a conspicuous landmark in public health history.

The toll which rheumatic disease exacted from industry could only be estimated from the fact that about 400,000 insured workers in England and Wales were ill from some form of the disease every year to the extent of being unable for the time being to follow their occupations. The total number of sufferers insured and non-insured was at least a million. The British alone treated over some 5,000 cases annually among the poorer classes those suffering from rheumatic disease. The problem of extending the use of the spas among the well-to-do was a matter for their own public organizations and the problem of making spa treatment more widely available to the poorer class was somewhat different. The suggestions at present being explored are the provision of hostels and of approved boarding houses subjected to a certain degree of medical control at spa centres. In both these respects the Empire Rheumatism Council could usefully help by educating the medical profession and by impressing upon public health authorities the value of spa treatment.

### Gout and Rheumatism of Metabolic Origin

The principal discussion at the Conference was on gout. It occupied a whole day and Professor F. R. FRASER presided over the opening session. He said that there had been no therapeutic advance in the treatment of gout since Wollaston in 1797 observed that the uric acid excretions contained urates and attention was directed to nitrogen metabolism in the metabolism of gout. Since the beginning of this century no great advance had unravelled so much with regard to metabolism that the clue to the pathology of gout seemed to be lying before them unrecognized. That was the relation to both acute and chronic uric acid was accepted but the mechanism of the relation was not

quite unsolved and the factors that determined the type and distribution of arthritis and of non-articular rheumatism in the individuals who suffered from gout were also unknown. If the answers to these questions could be given the key to many mysteries in the whole field of arthritis and of rheumatism in general would be forthcoming.

SIR WALTER LANGDON-BROWN, in an opening paper, said that the diminished incidence of gout had naturally led to a diminished interest in the subject. The last time he saw any considerable number of cases of gout was in 1919, when war-time food restrictions were removed, apparently some predisposed individuals had lost their tolerance for a full diet. Some of the diminished incidence was only apparent, and was explained by more accurate diagnosis and the application of more exacting criteria. X-ray examination had shown that cases of alleged gout might be of other forms of arthritis, and the alarming cases of so-called "suppressed" gout were now generally regarded as due to uraemia or myocardial failure. Sir Walter entered upon a consideration of the evolution of nitrogenous excretion in human beings and the factors in the deposition of urates in the tissues. He concluded that some persons suffered from a congenital or acquired difficulty in disposing of their nucleic derivatives, the difficulty being not of destroying but of eliminating purins, possibly due to the loss of power to conjugate them suitably. This led to such an excess of uric acid in the blood that a low-grade arthritis was fanned into intense flame by the deposit of irritating biurate crystals in a structure already involved.

Just as the essential pathology of gout remained obscure, its treatment by colchicum remained quite empirical. In large doses it was an irritant poison, yet, although powerless to avert an attack, its influence on the pain and swelling of an acute gouty joint was often dramatic. Except for the introduction of cinchophen in 1908 there had been no major change in the treatment of gout since the value of colchicum was established in the sixteenth century. The most serious risk of cinchophen was the danger of toxic jaundice. Twelve years ago he reported two fatal cases following the continued administration of some cinchophen preparations. When certain safeguards, however, were observed, such as had been worked out by Graham—who showed that if the drug were given in doses of  $7\frac{1}{2}$  grains three times a day for only two consecutive days in each week the total increase in the output of uric acid was as great as from continued administration and toxic effects were not encountered—there was no reason why patients should be deprived of its undoubted benefits.

Dr MATHIEU-PIERRE WEIL (Paris) followed with a paper on the same lines. The attack of gout, he said, did not manifest itself constantly by hyperuricaemia. The part played by disturbances in the metabolism of uric acid had in any case been greatly exaggerated. An immoderate alcoholic intake, cold, physical fatigue, moral indiscretion, traumatism, simple muscular or even intellectual effort were, to the individual who was predisposed, more likely to be generators of an attack than the absorption of sweetbread, spinach, or cocoa. The speaker discussed generalized acute and chronic "rheumatism of a gouty nature," also mono-arthritis of a similar type, which, he said, was far from being exceptional, and he concluded by quoting a remark that between gout and rheumatism there was the distance that separated the admiral from the first mate. "Gouty rheumatism" constituted the intermediate ranks, of recent times the admirals had become scarcer, but the first mates had multiplied.

### "Gouty Rheumatism"

In the course of discussion Dr J FORESTIER (Aix-les-Bains) took exception to his compatriot's category of gouty rheumatism. Words, he said, were important in

medicine because they tended to direct the therapeutic measures. In France there had been a tendency to regard any patient over 40 with a chronic condition as suffering from gout if there were tophi, and from "gouty rheumatism" if there were not. Dr E P POULTON took up Sir Walter Langdon-Brown's remark that the diagnosis of the gouty diathesis was certain in the presence of a blood uric acid above 3.6 mg per cent and of tophi. He had a patient under his care with blood uric acid of 3.8 who was entirely free from gout. Dr SCHNEIDER (France) drew attention to the peculiar intestinal symptoms which, he said, were found in 80 or 90 per cent of gout cases—namely, a special type of colitis without serious irritation of the intestinal lining.

SIR WILLIAM WILCOX said that since the war dietetic and metabolic factors had played a smaller part than formerly in the aetiology of gout. It had been his experience in recent years that focal sepsis and toxic factors had a good deal to do with gout causation. "Poor man's gout" was often associated with infection. The threshold of uric acid in gouty subjects was very different from what it was in normal persons, and this fact might be of great importance in determining the deposition of urate crystals. With regard to the possible dangers of cinchophen, or atophan as it was sometimes called, it was important to bear in mind that tolerance diminished with increasing years. It had been his experience that the danger of cinchophen was much enhanced in elderly people. He had seen five grains three times a day taken every day for a week prove fatal in elderly patients. The danger was in the effect on the liver, causing degeneration of the liver cells and toxic jaundice, and they were indebted to Graham for his wise advice that cinchophen should be taken for two days only and then withheld, to be repeated later if necessary.

Dr C W BUCKLEY (Buxton) protested against the assumption that the rarefaction of bones in the region of the joints would enable either rheumatism or gout to be diagnosed. He thought a clear idea of gout was only to be obtained by proceeding from the basic proposition that gout was a disease characterized by excessive uric acid in the blood and its deposition in the tissues. It was easy to prove the excess of uric acid in the blood, not so easy to prove its deposition in the tissues, but if such deposition took place then local necrotic changes occurred which were the bases of the production of the symptoms of chronic gout. He believed an attack of acute gout to be an allergic manifestation, there was a pre-existing deposition of urates in the tissues, and owing to some, probably seasonal, variation in the metabolism of purin bases a reaction was set up with characteristic symptoms, sometimes constitutional as well as local.

### An Analysis of Gout Cases

Dr LESLIE C HILL (Buxton) gave a critical survey of ninety-three cases of gout treated during the last three years. A family history of gout was elicited in 45 per cent of the cases and of fibrositis in a further 15 per cent. No one particular occupation stood out prominently, though the relatively high proportion of publicans supported the orthodox attitude towards alcohol as a factor in causation. Only three of the women patients (twenty-one out of the ninety-three) showed symptoms before the menopause. Articular gout was diagnosed in 61 per cent, abarticular gout in 16 per cent, mixed gout in 22 per cent. In more than one-half of the male cases the onset was sudden, in women gradual onset was more common. Most of the initial attacks occurred at night. Spring was by far the commonest season for acute attacks, autumn a poor second. In about 90 per cent of the cases the blood uric acid was 4.5 mg per 100 ccm of blood or over. The association of gout with glycosuria was noted by its absence in this series. He concluded that as the group of abarticular and mixed gout showed the same aetiological, clinical, and biochemical features and the same

therapeutic response as the more classical varieties there appeared to be no reason to deny a gouty basis for the fibrositis seen in these cases.

Dr HUBERT GIBSON and Dr G. D. KERSLEY (Bath) presented a clinical and pathological study of a series of cases. Of fifty-four cases of true gout 24 per cent had a family history of the same condition. Acute onset with complete remission occurred in 75 per cent; the onset following injury, infection or worry, sometimes the ingestion of particular foods and drinks. The age of onset was most frequently between 40 and 50. Only 24 per cent had tophi. Clinically there were cases grading off into other types of rheumatism suggesting that gout was more a syndrome than a disease. After discussing the pathological findings, Dr Gibson gave it as his opinion that by a consideration of the erythrocyte sedimentation rate, the polymorphonuclear neutrophil percentage, the red-cell volume and the formalin test chronic rheumatic diseases could be placed in the following order of their deviations from normality: (1) fibrositis, (2) osteoarthritis, (3) gout, (4) the gouty basis group, (5) rheumatoid arthritis, (6) spondylitis ankylopoietica. Dr Kersley who had undertaken the clinical part of the investigation said that the criticism would probably be that a number of cases were included which were not true gout.

In some general discussion Dr NOUB FARAH (Alexandria) said that gout was a definite entity tending to disappear with a healthier regime and more physical exercise while rheumatism of metabolic origin was a vague generic expression including many factors concerned with intoxication. Dr FLORENT COSTE (Paris) pointed out how greatly the incidence and clinical character of gout varied from country to country. One point on which the textbooks had made a mistake was in associating the disease with constipation. It was much more often associated with an irritable colon and frequent and urgent motions.

Dr JOSEPH RACE (Buxton) remarked on certain differences between gout and rheumatoid diseases in general from the point of view of heredity and of geography. For example rheumatoid disease was just as prevalent north of the Tweed as south but gout north of the Tweed was practically non-existent. Dr DOUGLAS COLLINS (Harrogate) said that he had aspirated the joint fluid from small and large joints at the stage of an acute gouty attack and had found it as full of polymorphonuclear cellular exudate as in any other kind of infective arthritis except those in which there were actual organisms in the joints. The inflammation was the same as inflammation of any other kind. The reaction it occurred in the synovial tissues gave rise to the proliferative changes which were to be expected and therefore it was no matter of remark that the later stages in the histology of gouty arthritis and rheumatoid arthritis should be similar. Professor ANDRONESCU (Bucarest) called attention to the aetiological factor of insufficient respiration. Failure to breathe properly could be the basis of almost any morbid process and should be considered in the aetiology of rheumatism.

Dr R. J. WEISSENBACH (Paris) and Dr F. FRANÇON (Aix-les-Bains) presented a paper on the radiographic aspect of gouty foot (the thorn foot). In the skiagram in profile the tarsus was spiked on its upper surface with osteoblastic protuberances usually grouped two by two forming a sort of crater. In the seven cases described the gout generally manifested itself in two or three annual typical attacks.

#### Incidence of Gout

At the second session of the Conference presided over by Sir HUMPHRY ROLLESTON several Continental workers gave their experience of gout. Dr GUNAR KAHLMETER (Stockholm) said that only twenty out of 1,000 rheumatic cases in the four great general hospitals of his city were cases of gout and in fourteen years private practice he had seen only seventy cases. Dr J. VAN BREEMAN

(Amsterdam) recalled the names of some famous men who had been afflicted with gout—Frederic the Great, Goethe, William Pitt, Sydenham, Kant among others. In nearly all countries the incidence of gout had declined and when it did appear it was less severe. The modern physician was untrained to recognize its varieties so that a number of sufferers never had their malady identified. In some countries cases of gout appeared to be rampant only by tophi elsewhere there was mere gout without tophi.

A paper by Professor GERONNE (Wiesbaden) was read in his absence by his colleague Dr KERNAT. He pointed out the connexion between gout and other metabolic disorders especially those occurring round about the menopause. One metabolic disorder which should be considered in relation to gout was the imperfect digestion of fats. Another form of arthritis clearly metabolic was alkaptonuria. A connecting link between all these forms of arthritis was that they were hereditary in the same sense as gout. Another distinguished absentee whose paper was read in his absence was Dr ERNST FREUD (Vienna) who contested the common view that gout was a familial disease. Out of 120 cases of gout in 10 years he had met with a familial factor in seven only. In 25 per cent of cases of gout he had found none. During ten years he had seen eleven cases of true gout in women all showed increased uric acid in the blood. Attacks of gout not seldom followed infections such as scarlet fever and diphtheria in which cases an allergic reaction might be assumed. He had found a combination of gout and rheumatoid arthritis in a few cases, one of them a man of 33.

In further discussion Dr PRICE (Bristol) described nine cases of congestive heart failure in which patients had been put on salyrgan and ammonium chloride for oedema. A brisk diuresis followed and each of the patients developed an attack of acute gout. Some of them subsequently had a history of recurrent gout over a long period. A return to oedema and increasing signs of failure occurred after the gout attack followed by death within a period of from one to six weeks.

Dr J. FORESTIER (Aix-les-Bains) said that from statistics published by his grandfather in 1850 it appeared that out of 800 rheumatic cases he had had only seven cases of gout. His colleagues in Aix-les-Bains and himself found a similar proportion to day. Not enough had been said about the influence of alcohol. Half or more than half the middle class patients who came to him for gout were proprietors of saloons. Dr PHILIP HENRI (Mavo Clinic) said that the chief diagnostic criteria were the characteristic patterns of the single and subsequent attacks and the response to treatment. The uric acid index and the presence of tophi were of less importance and x-rays were not of much help. Cinchophen was the subject of much controversy in the State. The truth appeared to be that some needed it and could not get along without it, while for others it had no value. Dr E. P. POULTON said that his colleague Dr W. E. B. LLOYD had found in carrying out certain special methods of examination that in an attack of gout there was a fall in the output of uric acid but a rise out of all proportion to such fall in the uric acid in the blood. Dr RUPERT WATERHOUSE (Bain) referred to a Continental observation that the amount of uric acid in the blood was estimated in the blood corpuscles and the amount of plasma varied at different periods during an attack of gout—that is to say the amount of uric acid in the plasma diminished whilst that in the plasma increased. He had himself repeated this observation and he could not find the figures obtained.

#### Jaundice in Relation to Rheumatism

At the final session of the Conference presided over by Sir WALTER LANGDON BROWN groups of related subjects were taken. The one that excited the

discussion was jaundice in relation to rheumatism Dr PHILIP HENCH (Mayo Clinic) said that when patients with rheumatoid arthritis or primary fibrositis became jaundiced their rheumatic symptoms were rapidly, markedly, and generally completely alleviated for some weeks or months—a phenomenon casually mentioned by, among others, Wishart\* (*British Medical Journal* 1903 1, 252) Dr Hench summarized his observations on thirty-one rheumatic patients who experienced the phenomenon and—of equal importance—on four patients with rheumatoid arthritis and nine with other types of articular and neuritic complaints who were not relieved Symptomatic remissions lasting from 5 to 82 weeks occurred in nineteen cases of rheumatoid arthritis in which intrahepatic or obstructive jaundice lasted an average of nine weeks Remissions lasting 4 to 104 weeks occurred in nine cases of fibrositis in which the jaundice lasted an average of 5.6 weeks The degree of symptomatic relief was complete for all the fibrositic and for almost two-thirds of the arthritic patients The remarks of the patients were significant "When jaundice came in at the front door rheumatism went out at the back" "I would trade my rheumatism for jaundice any day" The phenomenon was apparently more dependent on the quantity than on the type of the jaundice He added that there was no particular rationale for the use of "artificial jaundice" in rheumatic disease, but the history of the therapeutics of rheumatoid arthritis was full of the ghosts of "rational treatments" which should have helped but did not In this instance, thanks to one of Nature's revealing "slips" or "tricks," a return to the empirical might be of use The responsible agent and the mechanism whereby it operated had not, however, been identified He described some work on induced hyperbilirubinemia, it was a rather crude and inconsistent approximation to the more dramatic and complete effect of spontaneous jaundice It was by no means a 'control of arthritis, nor was it a practical procedure, being expensive and inconstant As a piece of research it had its promising features, but to exploit the use of bilirubin and bile salts for the treatment of arthritis at present was unwarranted and undesirable

Dr BARNES BURT (Bath) said that following a letter by Dr E. A. Addison which appeared in the *British Medical Journal* a year ago, suggesting an explanation of epidemic jaundice—namely, the eating of Spanish chestnuts—he procured two sacks of this fruit and tried it on certain rheumatic patients Unfortunately, the only person who developed jaundice at all was the sister in the ward! Professor VEIL (Jena) referred to a case in which the appearance of jaundice in the course of severe rheumatic fever complicated by meningitis was associated with a fall in the temperature and the disappearance of both the rheumatic and the meningitic symptoms He thought the phenomenon could be traced back to something very fundamental that happened in the liver Dr NUJIB-FARAH (Alexandria) thought the explanation might be found in the bilirubin in the blood In typhoid fever he had found the bilirubin low, in certain cases of rheumatic fever high It was a defence mechanism constantly varying according to the nature of the invading organism to be overcome Dr JOSEPH RACE (Buxton) said that the clue might lie in comparing the remissions which occurred owing to jaundice and those which occurred during pregnancy The only link appeared to be that bilirubin was a member of the same chemical group of substances in some others of which in pregnancy, changes occurred, cholesterol was a member of the same group

#### Circulation in Relation to Arthritis

Dr RALPH PEMBERTON (Philadelphia) said that the widely prevalent view which attributed some of the

symptoms of rheumatoid disease to disturbances of the peripheral circulation received support from much clinical and experimental data Important consequences followed from the derangement of the circulation After surveying the wide range of circulatory influences in arthritis, following the decreased rates of exchange of materials between the tissues and the blood as it passed through the periphery, Dr Pemberton said that although therapy should not be directed primarily, or chiefly, to the circulatory deviations, such a consideration should be part of the broad attack which envisaged the patient as a whole provided optimum conditions of rest and nutrition, and removed or controlled precipitating or contributory factors He emphasized the importance of rest "*Requiescat in pace* would do a great deal more good placed at the head of the patient's bed than on his tombstone"

#### Rheumatic Disease and the Voluntary System

The only discussion of a medico-political character took place on an address by Professor STANLEY DAVIDSON (Aberdeen) entitled 'Can the Problem of Rheumatism be Solved by the Voluntary System?' In Scotland, he said, 14 per cent of the invalidity of insured persons was due to rheumatic diseases, with a loss of three million working days a year Recently he had ascertained certain figures as a result of a questionnaire to a number of practitioners in North-East Scotland with regard to the number of new cases If their statistics were representative of the whole of Scotland and the month during which they were taken was representative of the whole year the annual number of new cases was 375,000, being 28,000 of rheumatic fever, acute and subacute, 24,000 of rheumatoid arthritis, 29,000 of osteoarthritis, and 294,000 of muscular rheumatism The only real facilities available were treatment by general practitioners and in voluntary hospitals All would agree that physiotherapy was needed at a certain stage in the treatment of rheumatism, but under national health insurance not even massage was provided, let alone more expensive forms of physiotherapy Nobody would suggest that voluntary hospitals could supply the need They had not an adequate number of men trained in physiotherapy, and many physicians on the staff of voluntary hospitals had little interest in the group of rheumatic diseases In Scotland the radiologist was usually in charge of the physiotherapy department, and however good he might be as a radiologist he was frequently ignorant of rheumatism and the methods of treating it The spas were relatively inaccessible to the large areas of working-class population He pleaded for the provision by local or national authorities of rheumatic clinics in charge of specially trained full time medical officers, and additional institutional accommodation where necessary He added that this did not imply that the voluntary hospital system would not have an important part to play in collaboration with the municipal clinics

Professor R. B. OSGOOD (chairman of the American Committee for the Control of Rheumatism) said that in Massachusetts, with a population of  $4\frac{1}{2}$  millions, chronic rheumatism led all other diseases as an economic, social, and medical problem The legislature had at last consented to give a subsidy to existing voluntary institutions so that a certain number of beds might be provided for the study and treatment of rheumatic diseases Dr J. FORESTIER (secretary of the French League against Rheumatism) said that the League was now recognized as a medical society of public utility which might receive endowments and public grants The French legislature provided facilities for the study of cancer, tuberculosis and venereal disease, and now rheumatic diseases were being included in the same provision

#### Miscellaneous Papers

Before the Conference ended three miscellaneous papers were presented under a "ten minutes rule" One, by

\* In a short note Dr John Wishart wrote 'When jaundice of an obstructive type becomes fully established in the system of a patient suffering from chronic rheumatism rheumatoid arthritis, or muscular rheumatism the pains characteristic of these diseases disappear entirely'—ED, *B.M.J.*

Dr LEVINHAL (Bath) recounted certain serological investigations carried out in the research laboratory of the Royal National Hospital upon sensitization and immunity. Dr W S C COPEMAN described certain toxic reactions to gold injections. Skin lesions had attracted his attention most. These might take the form of an erythema sometimes local and sometimes generalized which in the more permanent lesions might become purpuric. Eosinophilia was an indication that a rash was likely to occur but it was too late to be of any use. Dr GERALD SLOT mentioned some work on the treatment of sciatica. He had found of considerable value the method worked out by Evans and others of epidural injections followed later by manipulation. Under evipan anaesthesia an epidural injection of novocain was given. normal saline might be used instead, but novocain induced a little less pain.

#### Civic Banquet

The Mayor of Bath (Captain Adrian Hopkins) entertained the members of the Conference to a banquet at the Guildhall when the toast of The Conference was proposed by Mr C G MACKAY chairman of the Royal National Hospital who described the developments which are impending whereby the hospital will be re-erected and extended close to the hot springs. The toast was supported by Dr ALDRED BROWN who welcomed the visitors on behalf of the staff of the hospital and the medical profession of Bath.

Lord HORDER, in response, said that it was imperative that the hospital should be rebuilt at as early a date as possible. The conditions under which the medical staff did their work were wholly inadequate. There might be some people who questioned the right of the hospital to describe itself as national but in fact less than 4 per cent of the admissions came from Bath and its immediate vicinity. The patients came from fifty different counties in Great Britain and Ireland. The amount received for the appeal fund stood at £67,000 but this was less than one third of the total required. The lay out of the new hospital was excellent conforming to most if not all of the criteria by which he judged a modern hospital. A site would be available later for a paying patients' annex. No lay out of a modern hospital should be passed which did not provide for those who had been called the new poor.

Professor R B OSGOOD of Boston U.S.A. who also responded said that the exact causes of rheumatic diseases were still unknown or unproved but the effect of many measures of relief perhaps of control was understood. It was the present task to discover and eliminate as many of the background causes as possible. Above all it must be remembered that each case presented an individual problem for which the individual physician must be responsible also that orthopaedic surgery and physical therapy had an important part to play in the preservation of function and again that there was work to be done on the neurological and psychological side. He found great encouragement in the present awakening of widespread interest in rheumatic diseases.

The historical and literary associations of Bath were eloquently woven into the speech of Sir WALTER LANGDON-BROWN in proposing the health of the hosts and the Mayor in his reply touched on the history of the beautiful hall in which the company had met and of the city plate which was prominently displayed. He also mentioned that in 1784 the number of physicians and surgeons practising in Bath was twenty three as against 107 to-day.

Before leaving Bath the visitors attended a well arranged clinical meeting at the Royal National Hospital when cases were shown by Dr Aldred-Brown, Dr J B Bennett, Dr P W McKee, Dr J Barnes, Burt, Dr G D Kerslev, and Mr C E Kinderlev. A demonstration was also given of hydrological methods at the bathing establishment.

## INTERNATIONAL CONGRESS ON RHEUMATISM AND HYDROLOGY

### CONCLUSION OF OXFORD MEETING

The Oxford Congress the first part of which was reported last week (p. 743) continued until March 31 when it was followed by the similar meeting at Bath. The whole of the latter part of the proceedings was occupied with a discussion on juvenile rheumatism. The remarks of the openers have already been briefly summarized.

#### Juvenile Rheumatism Pathological Aspects

Continuing on the pathological aspects Dr G H EAGLES (Lister Institute) said that while various ages it had been suggested from time to time as the causal factor in rheumatism all of them left some element in causation unexplained. All the suggested organisms concerned in including streptococci when tried experimentally on animals failed to repeat the infection. Therefore it seemed reasonable to pursue the idea of a virus. The agglutination phenomenon was obtained with certain suspensions of virus like particles in serum from rheumatic fever, rheumatoid arthritis and chorea but on inoculating monkeys with these suspensions some doubtful clinical signs were produced in only three out of a series of thirty five. Post mortem examination revealed what might have been an Aschoff node but it could not be said that rheumatic fever had been produced in monkeys. The failure to obtain a clinical result despite the serological reaction might be explained either by supposing that these were not true virus particles or that they were virus particles but not capable of infectivity. I do not want to arrive at a conclusion with the idea that I think a virus is the cause of rheumatism said Dr Eagles. I do not know the cause—nor does anyone else.

Dr W H BRADLEY who had co-operated in the experiment said that the agglutination phenomenon was a real one capable of being observed and repeated. Dr Bradley proceeded to describe a case furnishing some evidence that the apparent anaemia and pallor in rheumatic fever was due to an increase in plasma volume. Dr A C LEMMONY (Glasgow) showed histological sections of the case of a woman aged 20 who died of extremely severe rheumatic infection in the seventh month of her pregnancy. In the foetus were found microscopical appearances of a definite though non specific valvulitis. The mother's illness had been of four weeks duration starting with little more than fleeting joint pains as a sequel to a chill. Professor VEIL (Jena) referred to the existence of pre-rheumatic states obscure illness with indefinite symptoms and Professor LOEWENSTEIN (Vienna) mentioned the value of evidence from histological examination of glands in the neighbourhood of the joints affected.

#### Clinical Aspects

In the discussion on clinical aspects with Dr LEONARD FINDLAY and Dr H. GRENET as rapporteurs Dr GERMAN BLECHEMANN (France) commented on the frequency with which an attack of scarlet fever had been followed within a few days or weeks by articular rheumatism often with cardiac complications. Professor C BRUCE PERRY (Bristol) mentioned the frequency of antecedent tonsillitis. Recently adopting a more searching examination of his histories he had found an antecedent sore throat in 75 per cent of first attacks of arthritis or chorea and in 50 per cent of relapses. In chorea such a history was found in 100 per cent. In the case of articular rheumatism such a history was forthcoming in 100 per cent. As for exanthematous diseases as a whole appeared to be more common in females than in males in the West of England at all ages. One sex differentiation was the greater frequency of infection of the aortic valve in boys. This was found in 10 per cent of male cases of chorea and only in 7 per cent of female cases. In opening the discussion Dr FINDLAY said that the evidence on the existence of a rheumatic virus

lesion, but this speaker believed, that there was a genuine, though rare, involvement of the lungs in some cases, and not always as a terminal event, nor to be explained on the basis of congestive cardiac failure

The discussion was concluded by Dr S SIWE (Sweden), who said that quick subsidence and extreme variability in the same individual were features of rheumatic infection in childhood. The sedimentation rate was at present the most convenient means of following the course of such infections, but chorea did not speed the sedimentation rate. Medical opinion in his country still adhered to the value of salicylates, which had more than a symptomatic action. He emphasized the necessity for long and careful supervision, with rest in bed which in children implied hospital and convalescent accommodation

### Therapeutic Aspects

The discussion on treatment was opened by Dr WILFRID SHELDON (London). He opened with a definition of juvenile rheumatism—the proceedings of the Congress had rather pointedly suggested the need for a definition—as embracing three clinical conditions: acute rheumatic arthritis (in this country called rheumatic fever), rheumatic disease of the heart, and rheumatic chorea. A fourth group of symptoms was subacute rheumatism, indicating a pre-rheumatic state, with vague limb pains, often combined with evidence of debility. In the general principles of treatment of acute articular or cardiac rheumatism rest in bed remained the sheet anchor. Since the introduction of salicylates sixty years ago no drug had reached the same popularity. Combined with alkali it should be pushed in acute articular rheumatism, and might be used in smaller doses for the relief of pain in carditis. The effect of aspirin was no greater than that of sodium salicylate, and it had the disadvantage of being incompatible with alkalis. Pyramidon had not gained popularity in this country except in the treatment of chorea. His own experience of sulphanilamide in this connexion was disappointing and the results of vaccine and serum therapy up to date had been inconclusive.

Professor DE HORVATH said that in Hungary juvenile rheumatism was far from being as rare as it was in Northern and Western Europe, but rheumatic disorders were tending to increase and the type of rheumatism was becoming more severe. One unusual complication increasingly noted was hepatitis. Treatment with gold preparations had resulted in no great improvement, and required, especially with children, most circumspect handling.

Dr CAREY SMALLWOOD described the arrangements and routine at the Baskerville rheumatic colony, Birmingham. Did the advantages of colonization outweigh the disadvantages? Children from poor overcrowded homes who had reached the stage of convalescence from a recent acute carditis would reap great physical and educational benefit from long-continued care in a colony, but for the child with a scarred heart, whose rheumatic infection had died down, colonization might be extremely dangerous. Dr L SCHMIDT described a clinic for juvenile rheumatism which had been established at Pistany with the help of the Ministry of Health of Czechoslovakia. He suggested that rheumatism might appear in certain children under slight and confusing symptoms owing to a difference in the reactive power of the child. Very slight symptoms, including rises of temperature of even a quarter of a degree should not be disregarded in a child suspected of a rheumatic tendency. He warned against the indiscriminating use of massage and baths.

### Postural Exercises

Dr WARREN CROWE (London) said that, having seen the work of Goldthwait and Loring Swaim at Boston, he had adopted some of their exercises for a number of patients at the Charterhouse Rheumatism Clinic and elsewhere with good results. In their books a long and com-

plicated system of postural exercises was described, but these could actually be reduced, for most people, to two basal exercises of extreme simplicity, with a third for the narrow-chested, shallow-breathing asthenic type. They were performed lying on the back on a plane surface. Dr Crowe projected a film beginning with some diagrammatic silhouettes showing faulty, improving, and good posture, and passing on to the exercises. The exercises were of a simple type designed to increase the activity of the circulation, to eliminate the lumbar curve and strengthen the abdominal muscles, and finally to expand the thorax and enlarge a narrow costal angle. If these exercises were carried out regularly for two or three minutes night and morning a correct posture was easily acquired. The common attitude, in which the lumbar and dorsal curves were exaggerated, the knees were slack, and the abdomen was sagging, would be gradually replaced by an upright and alert bearing—in Goldthwait's words "Stand tall, weight on the balls of the feet, abdominal muscles contracted, lumbar curve flattened, chest and head up, and chin in." In rheumatic children the exercises should begin at the earliest possible moment compatible with the cardiac condition.

Dr W R F COLLIS (Dublin) discussed "growing pains"—a term in use before the days of scientific medicine. Subacute limb pains occurred in children usually between the ages of 3 and 14, and might be divided into three groups: (1) those appearing in attacks of subacute polyarthritis, (2) those appearing in attacks of rheumatism of the adult type, but not at all uncommon in children, and (3)—the largest group—pains due to debility, including those arising from deficiency diseases. Acute rheumatism really accounted for only one small group of cases of growing pains. Dr E P POULTON was doubtful whether growing pains of any kind could be separated from the rheumatic state. Dr CAREY SMALLWOOD said that in his view 95 per cent of children who had growing pains showed no evidence of heart rheumatism. Often the pains were a psycho-neurological reaction to a bad environment.

Dr GUNNAR EDSTROM (Sweden) mentioned the use of gold therapy. At the rheumatic clinic of the University of Lund sixty-nine cases of rheumatoid arthritis had been treated with gold salts (solganol) during 1937. Of the fifty-nine which received the full treatment (at least 2 grammes of solganol, never in larger doses than 0.25 gramme) good results were obtained in thirty-three and improvement in eighteen. In forty-one cases there were certain complications, including, in five cases, thrombocytopenia or granulocytopenia, but, these notwithstanding, he regarded the treatment as preferable to that with sulphanilamide or with vitamin B.

Dr J FORESTIER demonstrated the orthopaedic treatment given in severe cases of rheumatoid arthritis in children at Aix-les-Bains. By the use of successive plaster casts it had been possible to effect great improvement. A complete cast was kept in position for only eight or ten days, then half the plaster was cut away, retaining the posterior part as a splint. In this way ankylosis was prevented.

### Social Aspects of Juvenile Rheumatism

In opening this discussion Dr F J POYNTON remarked that the incidence of the disease in Great Britain was not known for it was not notifiable, and in view of what had taken place at the present Congress, when it was evident that the experts did not know what it was, he would not advise that it be made notifiable. As for causes, he believed the British climate to be largely responsible, with its swift unexpected variations, and the cold damp, which favoured tonsillitis and catarrh. The disease was more frequent among the poor, but the "poverty complex" did not explain all the facts of causation. Of gross faults of what he called the "microclimate" he mentioned overcrowding, which was held by the late Carcy Coombs to be more important than damp in juvenile rheumatism.

As for nutrition he had not thought that the rheumatic children under his care were in general ill nourished but Sir John Orr's statement that a completely adequate diet was only reached at an income level above that of 10 per cent of the population caused one to revise one's notions. The present push for swimming or bathing pools ought to be watched from the point of view of the rheumatic child who was sensitive to sudden changes of temperature and to prolonged stay in cold water.

After Dr MARIEL ORY and Dr A. VORGAARD had described the social provision in Belgium and Denmark respectively, Dr C. E. THORNTON of the Public Health Department, London County Council described the rheumatism scheme of that authority. The treatment, care and education of rheumatic children cost London £220,000 a year. In June of last year there were under supervision by the school doctors 2,000 children with another 5,000 at the special supervisory centres and 890 actually under treatment in the rheumatism hospitals. The rheumatic area of London followed closely the southern bank of the Thames with some of the poorer areas on the northern bank, the north west was relatively exempt. The seasonal curve reached its lowest in July and was almost the inverse of the sunshine curve for London. The hospital provision made by the Council consisted of 900 beds being 650 for acute cases and 250 for doubtful and convalescent. There were twenty rheumatism centres ten entirely under the control of the Council and ten run in co-operation with voluntary hospitals.

In the course of the session a message was read from Professor Kontchalovsky of the USSR and the Committee for the Study and Control of Rheumatic Diseases in Soviet Russia sent a report specially prepared for the Oxford Congress on the combating of rheumatism among Soviet children. The first clinic for juvenile rheumatism was opened in Moscow in 1934 and there are now clinics in many other cities while in Moscow a special clinic for the rheumatism of adolescence is projected.

## MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY

### Annual General Meeting

At the annual general meeting of the Medical Sickness, Annuity and Life Assurance Society, held at its offices, 360 High Holborn, W.C.1 on March 29, Dr F. C. Martley, chairman of directors, said that the year as a whole had been auspicious and although there was nothing spectacular in the new business figures a steady volume had been maintained. The total life assurances showed a small increase and the sickness assurances a very small decrease but during the present year after the report and balance sheet now presented were closed a really substantial increase in both these classes of assurance had been experienced as compared with the corresponding period in 1937. In the life assurance fund during the year under review the new sums assured had amounted to £500,000, the claims paid had been £14,018 and the premium income had increased to £123,207. The new business in the sickness fund was slightly less than in the previous year but the previous year had been exceptionally good. The benefit paid away during 1937 was greater being explained apart from the increase to be naturally expected by the influenza epidemic during the early part of that year.

Dr Martley called attention to the item Loans on medical practices which as shown in the balance sheet had increased to £225,922—a net increase of just under £40,000 over the previous year. More business than ever was being done in this field, often more applications were received than was altogether convenient especially from the point of view of the time of the staff which was taken up in investigating them. Dr Martley concluded with a reference to the investment policy of the Society. The funds were growing rapidly and stood at over one and a half millions. At the present rate

of growth they would if affairs pursued the natural course be well over two millions by the next valuation. There were anxious times for those connected with the administration of insurance and the directors felt that it was in the best interests of the Society to follow a cautious policy in maintaining a balance between the holdings in good industrial securities and in Government stock.

The report and accounts were received and adopted and on the motion of Dr G. de Becqulre seconded by Dr Fairfield Thomas the two directors who retired by rotation—namely the chairman Dr F. C. Martley and Sir William Willcox—were re-elected. The chairman then proposed that the meeting recommend the payment of an interim bonus of 10% on all with-profit policies for permanent sickness and accident insurance and life assurances becoming claims during the year ending December 31, 1938. This having been agreed to Sir William Willcox proposed a vote of thanks to the staff of the Society mentioning the manager and secretary Mr Bertram Sutton who he said had been with the Society since its inception and Mr Heath and Mr Venus. This was carried with acclamation.

## Reports of Societies

### LUNG ABSCESS DIAGNOSIS AND TREATMENT

At the meeting of the Medical Society of London on March 28 with the President Mr J. E. H. ROBERTS in the chair a discussion took place on the diagnosis and treatment of lung abscess.

Dr JAMES MAXWELL defined lung abscess as non-tuberculous suppuration with cavitation occurring in lung tissue. The causation of lung abscess could be approached in two ways, by animal and by clinical experiment. Most of the animal experiments have seemed to be entirely misconceived. The animals used were naturally quadrupeds, their trachea was naturally horizontal and there was absolutely no guarantee that a result which applied to an albino rat applied to a human being. The cough reflex in humans was a most important way of keeping the respiratory passages clear out in the animal a cough was quite an unusual event—so unusual that in the case of a Derby favourite it was a matter for the 'Stop Press'. Clinical study gave the clue to the causation of abscess. He entered in particular of the condition now becoming well recognized as pyogenic pneumonia an inflammatory consolidation of the lung of a sort. With such inflammatory consolidation the future of the patient would depend not only on the local resistance in the lung tissue but also on the general resistance. Dr Maxwell outlined the position on the following table:

Resistance to Infection		
General	Local	Resons
Good	Good	Pneumonia
Good	Bad	Lung Abscess
Bad	Good	Pneumonia
Bad	Bad	Septicæmia

He was coming to look on pneumonia as the precursor of most of the acute inflammatory lung troubles. It did not really matter how the organism got into the lung, whether by aspiration or the blood stream, the result would be the same according to the extent of the patient. Any condition which caused infection of the lung would cause abscess if the resistance in the lung tissue was not sufficient to overcome the infection. He listed the causes of lung abscess as follows:

- (1) Lesions involving the respiratory tract
- (2) Abdominal conditions
- (3) Sequel to peripheral septic conditions
- (4) Lesions of the nervous group
- (5) So-called primary lung abscess

The diagnosis depended on the symptomatology, the signs, and the results of special investigation. Cough was a fairly common early symptom, for the first week or longer it might result from irritation of the bronchi and therefore be unproductive, but even at that stage there was surrounding congestion and therefore haemoptysis was to be expected. Then there might come a stage when there was sputum, appearing quite suddenly and in considerable quantity. Another symptom which might arise was pain in the chest, this helped to localize the lesion. Shortness of breath was not a very prominent symptom. Temperature varied very little, in some cases there might be a high temperature with rigor, but in many others it was possible to have quite a large abscess with little or no pyrexia. One symptom which was almost diagnostic, especially in an acute case, was that cough was induced by change of position. Among special investigations great help was obtained from bronchoscopy, which would not only make the diagnosis but assist materially in treatment. Radiology of the chest was also most important. Very often the shadow of the abscess was approximately circular and fairly well defined. The presence of a clear zone was perhaps the most important feature in the radiological picture of lung abscess. In the x-ray picture the lateral view was quite as important as the antero-posterior. The tomographic representation was also often of value. One investigation which was dangerous was the needling of the chest. This should never be done without the most serious consideration.

The evidence went to show that deficiency in the cough reflex was one of the factors which tended to promote infection. So far as post-operative lung abscess was concerned, very often pre-operative and post-operative medication was at fault. The giving of morphine, in his view, tended to diminish the cough reflex to an extent which allowed suppuration to occur. A certain number of patients with lung abscess, if left alone, would get rid of their abscess spontaneously, sometimes by absorbing the pus and sometimes by coughing it up. His plea as a physician was that cases should be watched as long as this was reasonably safe, and not operated on until there were definite indications for so doing. An abscess which would not diminish in size as a result of postural treatment seemed to be one in which surgery ought to be considered. While the initial bronchoscopy was extremely valuable, repeated bronchoscopy was a waste of time, because it was likely to be most effective in the same cases as were benefited by postural drainage alone. As to artificial pneumothorax, if the abscess was deeply situated, draining into a bronchus, and failing to resolve, then an artificial pneumothorax might help it to heal.

### Surgical Considerations

Mr R C BROCK said that from the textbooks one was liable to gather the impression that lung abscess quite commonly followed an operation, the inhalation of a foreign substance, or an attack of pneumonia. But in fact almost all critical observers agreed that the so-called primary lung abscess formed by far the greatest proportion of cases. No obvious predisposing cause was to be found. He was unconvinced as to any common association between true pneumonia and lung abscess. The term pneumonitis was a convenient and satisfactory one to explain the preliminary pathology. In the large group of abscesses of uncertain origin he had been impressed with the frequency with which gross oral or nasal sepsis was discovered, and he was quite sure that that was an important causal factor. In the radiological examination he emphasized the importance of the lateral view. In his own experience the commonest site of lung abscess was the apical branch of the lower dorsal lobe. The site second in frequency was the axillary portion of the upper lobe. Abscess of the middle lobe was rarely seen as a primary abscess, though it was not at all uncommon as a secondary one.

The treatment of lung abscess differed in no way fundamentally from the treatment of abscesses anywhere else in the body. The principle was to aid maturation and spontaneous discharge of the abscess by some simple means, but when it was realized that this was not going to take place by such means resort must be had to some form of surgical attack. Postural drainage to many people implied merely tipping the end of the bed, but it was only with an abscess in certain portions of the lower lobe that this device was of any value. Mr Brock indicated the postures which were of use for abscesses in different positions. A great deal of nonsense had been written about bronchoscopic aspiration. It was a valuable form of treatment, but too many people had the idea that it was a magician's wand. External drainage became indicated when it was clear from a study of the clinical and radiological condition of the patient that improvement was stationary or not to be expected.

### General Discussion

Dr F G CHANDLER drew attention to a condition which might be called suppurative pneumonitis, but in which there was no definite abscess, no cavity or definite collection of pus. He asked for suggestions as to how such a condition should be treated. Mr TUDOR EDWARDS said that he had never seen a true pneumococcal abscess of the lung, and he believed the majority of abscesses so described were inhalation ones. The guard of the larynx was not complete, and the cough reflex not entirely satisfactory. At any rate, cases of single, as apart from multiple, abscesses were largely caused by that type of infection. Dr P H MANSON-BAHR drew attention to amoebic abscesses of the lung, either primary or secondary to liver abscesses. Such cases might arise many years after people had left the tropics.

The PRESIDENT said that it had been the custom for many years for lung abscesses to be treated in a most optimistic spirit. Because a certain proportion of cases recovered spontaneously all cases had been kept waiting in the hope that they would make spontaneous recoveries, but during all this time the infection was continuing in the lung and producing irreparable damage. Operative drainage of lung abscess at an early stage was not a very dangerous procedure. He was not advocating indiscriminate operation on all cases, because he agreed that a considerable number did recover spontaneously. The primary treatment of a lung abscess was non-operative—postural, with drainage—but if there was evidence that the abscess was not draining it was necessary to go further. One good piece of evidence that an abscess was not draining was the fluid level in the cavity. If the fluid level persisted for fourteen days it was clear that the cavity was not draining efficiently. Apart from evidence as to the fluid level, if the patient was clinically improving and the radiographical shadow was getting less, then by all means non-operative treatment should continue, but if after a trial of fourteen days there was no clinical improvement or some clinical but no radiological improvement or if after some progress there was a relapse, then it was of no use proceeding with conservative treatment.

Dr BURTON WOOD said that the problem which distressed the physician was not so much the fixation of the abscess as the forms of pulmonary suppuration in which the abscess was much less clearly defined. The introduction of prontosil opened up a new field, and he hoped that some method would be found of dealing with the extensive pulmonary suppurations which constituted a more difficult problem than the abscesses with which the surgeon usually successfully dealt. Dr J G SCADDING joined with Dr Chandler in saying how difficult were the cases in which there was no definite abscess cavity. He mentioned one case which he said was a true wandering pneumonitis. These were the really difficult cases, and as for indications for treatment—well, there were none. Dr E R BOLAND related an interesting case in which a patient had lost his pulmonary abscess by cough

ing as a result of having his stretcher carried up in various tilted positions to the fifth floor of a nursing home.

Dr MAXWELL in reply said that although he had put primary abscess at the end of his table of causes it did not imply that it was the least frequent nevertheless he was surprised at the figure of 70 per cent which one speaker had mentioned. The suggestion he would make to Dr Chandler for dealing with the diffuse type of case he had illustrated was that ultra short wave diathermy should be used. The cases that did not resolve completely with this procedure were likely to break down and form a definite abscess.

Mr BROCK agreed that the treatment of suppurative pneumonia was a most difficult aspect of the problem. The diathermy loop was the most likely method to succeed. As to needling the needling of a lung abscess was very dangerous but in the type of case mentioned in which there was a diffuse black out and in which there seemed to be a chance of saving life if the cavity could be found he thought needling was excusable. The cases he had needled had always had a very resistant pleura, and no question of infection of the pleura had arisen. He had on occasion found a cavity as big as a hen's egg and after draining it the patient had recovered. Operation performed unsuccessfully without any accurate localization might be the most calamitous treatment but if care were taken to localize accurately the external drainage operation might be very simple in procedure and very dramatic in its results.

## THE ITALIAN ARMY IN ABYSSINIA

### Hygiene and Hospital Organization

At a meeting of the Royal Society of Arts on March 30 with Sir HUMPHRY ROLLESTON BT presiding Dr ALDO CASTELLANI KC MG (Hon.) (Count of Kisumu) who was appointed by Signor Mussolini High Consultant and Inspector General of all the medical units in East Africa and the Red Sea described in a lecture the hygienic measures and hospital organization of the Italian expeditionary forces during the recent Abyssinian campaign.

The war began on October 3 1935 and ended on May 9 1936 a few days after the fall of Addis Ababa. During this period the Italian troops on the northern front (Eritrea) and the southern front (Somaliland) numbered about 500,000. It is believed that this was the first time in history that so large a mass of white troops was transported to a tropical zone and in view of heavy losses from sickness in previous campaigns in tropical countries the situation was viewed with some misgiving. In 1890 the French lost in Tonkin more than one eighth of their troops owing to disease. In the French expedition to Madagascar in 1895 disease accounted for the death of more than one third of the army. In seven months of the Boer War (March to September 1900) out of a total of between 150,000 and 200,000 men disease accounted for over 5,000 deaths. During the Great War the East African Expeditionary Force with an average strength of 50,000 lost 6,300 men by disease as compared with 2,374 killed in battle.

It was fortunate said the lecturer that the head of the Italian Government realized immediately the enormous importance of medical preparation in a colonial war. The requests made to him for medical personnel and hospitals were immediately acceded to and in fact even doubled at his express command. Vast supplies of drugs disinfectants serums and vaccines were dispatched to Africa as well as hospital and laboratory equipment of every kind. During the war period the Italian army had 135 base and field hospitals each with medical and surgical wards a bacteriological laboratory and an x-ray department also fifty five small transportable hospitals

thirteen special surgical units fifteen x-ray ambulances four central institutes for special chemical and bacteriological investigation and twelve disinfecting stations. The navy had twenty hospitals and infirmaries along the coast together with eight hospital ships and the air force had twenty two infirmaries. The medical personnel in Africa numbered 2,484 of whom 2,205 were officers in the Royal Army Medical Corps and Militia. All the armed medical officers were required to take a course of instruction at the Hospital for Tropical Diseases in Rome before leaving for Africa. There were 284 nurses serving on board the hospital ships and in the base hospital and 100 hospital nuns also tended the sick while the regular hospital attendants and male nurses numbered 1,500.

### Sickness Prevalence

Malaria gave no serious concern to the Italian army though a number of the zones in which operated were badly malarial. The number of cases of primary malaria admitted to hospital was 1,241 and of relapses 1,075. There were twenty three deaths from pernicious malaria including blackwater fever. Quinine prophylaxis was insisted upon from the beginning every soldier received three tablets a day of quinine sulphate or bismuth chloride each tablet containing 0.2 gramme. At every meal the commander in chief and his staff officers ate an example by taking quinine regularly. The men were frequently paraded and a test of urine made to find out whether quinine had been taken.

The number of hospital cases of dysentery was 4,477 without a death. The great majority of these cases were of amoebic origin. First among the prophylactic measures was pure drinking water. Practically all the officers drank mineral waters which had been obtained in Italy. For the troops the local water was purified by boiling or some method of chlorination. The men were recommended to get into the habit of washing or disinfecting their hands with a 2 per cent solution of lysol or lysolorm after visiting the latrine or before having meals and lysol disinfection was strictly enforced on cooks and others serving in the kitchens. No vaccines were used the reason being that vaccines containing the Shiga-Kruse bacillus gave a severe reaction. With regard to oral vaccines the lecturer had not been able to convince himself that they were really efficacious. On grandmotherly precaution was adopted in the position for each soldier of a flannel abdominal belt to prevent chills.

Not a single case of cholera occurred before during or after the war. The cases of typhoid and paratyphoid infection numbered 48 with 161 deaths. One of the precautions taken was vaccination with mixed vaccine. No cases of typhus were reported thanks to the position of rigorous cleanliness. On the other hand the Abyssinian troops were known to have thousands of cases of typhus and louse infestation was common among them. There were only seventeen cases of relapsing fever with no deaths among the Italian troops but the Abyssinians were said to have had between 20,000 and 100,000 such cases. Small pox also occurred among the Abyssinians in great numbers but there was no case (which recovered) among the Italians. Fleas were almost completely absent—a result of the use of seven deaths—the virtual immunity being due to the effect of the sun under the prohibition of a complete attack except after sunset and the avoidance of travelling wherever possible.

Many cases of beriberi occurred among the Abyssinian troops but not a single case among the Italians during the war though one case developed after the war. Scour was rampant in the Abyssinian front but the Somaliland front but again no cases occurred among the Italians the chief reason for this immunity being that every soldier was given a lemon a day. The ration included a daily allowance of tea and biscuits and

potatoes fruit, beef, cheese, sugar, salt, olive oil, and coffee, with macaroni or spaghetti six times a week, rice once a week, condensed milk twice, marmalade twice, wine daily when obtainable, and brandy once a week. As major diseases were so low in incidence, more attention was paid to minor diseases, as, for example, such conditions as 'prickly heat' (lichen tropicus), for which menthol-alcoholic lotion was used, and dhobie itch, for which the parts affected were powdered with boracic acid.

#### Total Casualties

The total casualty list, for an army of 500,000 men, comprised 1,099 deaths on the field or from wounds and 599 deaths from disease," the term 'disease' including any injury or accident not caused by the enemy.

In conclusion the lecturer quoted statements made by Mr J L Rohrbach, correspondent of the United Press of America, who, after describing the ravages of disease in the Abyssinian army, where, he said, scurvy destroyed the army on the southern front and small-pox the army on the northern, while typhus passed from camp to camp, added, "It is obviously no exaggeration to say that one of the prime reasons for the Italian success was the continued health of their armies, due to the efficiency of their medical service. It also might be observed that medical science made it possible for white people to live in unhealthy climates under adverse conditions and to remain in better health than natives acclimatized by hundreds of years of continuous abode."

## Local News

### ENGLAND AND WALES

#### The Gloucestershire Scheme

A long and honourable period of service has been brought to a conclusion by the retirement of Dr J Middleton Martin from the position of Medical Officer of Health for the administrative county of Gloucester. Dr Martin assumed office in 1903, at first mainly in an advisory capacity, but very soon executive duties began to be added to him, beginning with the Midwives Act and the medical inspection of school children, and continuing through the years as his Council assumed new responsibilities in the field of public health which it was his function as their administrative head to translate into appropriate action. National health insurance, mental deficiency, dental treatment, venereal disease, maternity and child welfare, the care of the blind, and other activities all engaged his attention in turn, but his creative touch has been nowhere more apparent or more happy in its results than in his scheme for the extension and co-ordination of the medical practice of his county, with its chain of services covering the whole county area, based on the three large general hospitals at Bristol, Cheltenham, and Gloucester, and out-stations of hospitals over the county at which treatment is given weekly by the local practitioners and at which members of the hospital staffs attend periodically to give special services to patients grouped for examination. The scheme in its inception was recognized as a model by one of the Consultative Councils of the Ministry of Health. As it developed it established touch with the University of Bristol, and brought within its ambit the treatment of goitre, the rheumatic heart, maternity and child welfare work, and other activities. Orthopaedics is now well organized. In 1936 there were under review by surgeons 1,040 cases of deformity including fifty-nine poliomyelites—the aftermath of an outbreak of that infection during the previous year. Much has been said and written by many on the co-ordination of medical service and much drawn in diagrams

exhibiting circles, squares, and triangles joined by lines which somehow in the end lead precisely back to the point from which they started. But Dr Martin acted. While others studied the gale warnings he launched away and may justly be claimed as the pioneer in this country of a vitally important branch of organized medicine. His professional friends trust that he may long be spared to witness the widening expansion in other English county areas of the system for which he set so excellent a model.

#### Liverpool Tropical School

The thirty eighth annual report of the incorporated Liverpool School of Tropical Medicine (1936-7) constitutes a further record of a wide range of useful work. During the year 145 patients were admitted to the tropical ward of the Royal Infirmary, and many others were treated in the out-patient department. One hundred students from many parts of the world attended the various courses. Those in the DTH classes received additional practical instruction in village hygiene, surveying, and sanitary engineering at the demonstration area at Mellington, where an all-concrete house has been erected, a bore hole type of latrine installed, and a simple type of incinerator, suitable for village work, constructed. The recently inaugurated short courses of instruction in elementary tropical hygiene for non-medical people were attended by nineteen men and women. At the Sir Alfred Lewis Jones Laboratory, Freetown, Sierra Leone, recent work suggests that typhus is likely to prove a disease of considerable importance in British West Africa. Although much progress has been made, this work is still in its preliminary stages, and some time must elapse before even such fundamental points as the type of the disease and the nature of the vector are established with certainty. A research with great practical potentialities is being carried out by Dr A J Walker. This is a study of a disease affecting mosquitos which proves fatal to both larvae and adults. It is obvious that this investigation may produce results of considerable importance in the control of mosquito borne diseases. The laboratory is also responsible for the first ecological rat survey in West Africa, which was carried out during the period under review. The wise provision of long study leave for the West African Medical Staff enables its members to keep abreast of developments in other countries. For example, Dr T H Davey left the colony on study leave after an attack of typhus contracted as a result of his research work. He continued to work on typhus at the Pasteur Institute in Tunis, represented the School at the Medical Congress at Algiers, and prosecuted further studies in Hamburg. The report includes a list of twenty-seven original publications by members of the staff.

#### Industrial Foot Injuries Standards for Footwear

The British Standards Institution has been asked to set up a standard specification for safety footwear. This request was made unanimously at a meeting of manufacturers and users called recently on the initiative of the National "Safety First" Association, in conjunction with the Boot Trades Research Association and the Industrial Welfare Society. The importance of preventing foot injuries is emphasized by an inquiry recently carried out by the Sheffield Industrial Committee of the National "Safety First" Association, which revealed that over a group of fifty six firms the average proportion of foot injuries in non-fatal accidents was as high as 14 per cent, and it is known that proportions of 25 per cent and 30 per cent are not uncommon in individual cases. Over 11 per cent of non-fatal accidents in coal mines are foot injuries. Giving protection for the feet is the most simple and adequate way of avoiding these accidents which have many different causes. Many employers have realized this fact and for some years manufacturers have been supplying special 'safety boots'. These boots are of various types, but the essential feature of all of them is a hardened toecap, which will not collapse even if

a heavy weight is dropped on it. At present there is no standard of performance by which the various boots can be used, so that the new development should be welcomed by makers and users alike. In order not to stifle development the standard will not specify materials and construction but will only state, for instance, that the toe caps must withstand a certain weight dropped from a certain height and must satisfy agreed endurance tests. The maximum weight a man can carry—about 1 cwt.—dropped from his hands on to his toes may be taken as a basis of discussion.

#### Notification of Measles and Whooping cough in London

As stated in the *Journal* of March 5 (p. 534) the London County Council is proposing to require compulsory notification of measles and also whooping cough in London. At present compulsory notification of measles under orders made by the Minister of Health is in operation in eleven metropolitan boroughs only. In all but one of these boroughs notification is partial, being confined to the first case in the same household or institution within a period of two months. In three boroughs it is further limited to children under the age of 5 years. If the figures supplied by eight metropolitan borough councils where notification has been in operation for some years are representative of London as a whole it may be assumed that had notification on the same basis—namely the first case in the same household or institution within a period of two months—been in force throughout the county approximately 94,000 cases of measles would have been notified during the epidemic of 1935-6. The total number of cases therefor must have been far in excess of the 34,200 of which borough medical officers of health were informed during that epidemic. Whooping cough is compulsorily notifiable in five metropolitan boroughs but the notification is limited in two of them. The average number of deaths annually in London during the ten years 1927-36 was 527 from measles and 394 from whooping cough.

The Hospitals and Medical Services Committee in its report to the Council on the subject points out that measles and whooping cough are serious not only in themselves but in the complications and sequelae that frequently arise. Compulsory notification has an undoubted psychological effect on the attitude of the general public towards infectious disease notifiable diseases being regarded more seriously than non-notifiable ones and a greater readiness to obtain medical advice and treatment is shown. It is the opinion of the committee that the Minister should be asked to make regulations to render measles and whooping cough compulsorily notifiable on a uniform basis throughout London. It is not proposed that the regulations should apply to German measles and it is considered sufficient if the notification is limited to the first case occurring in the same house or institution within a period of two months as this will enable the necessary contact to be established with the borough medical officers of health. It is believed that the compulsory notification may result in a decrease in the number of complicated cases requiring admission to the Council's hospitals. The annual cost of the repayment of notification fees is not expected to exceed £8,000 a year.

#### Hospital Services and Boundaries

The special body called the Provisional Central Council, set up to consider and advise how the recommendations of the Sankey Commission can be made effective, has held two meetings. It has issued a letter to the secretaries of the existing regions of the British Hospitals Association, copies of which have been sent to the chairman and secretary of every voluntary hospital in England and Wales. In this letter it is asked that special meetings should be called for the purpose of considering the present boundaries of the region, the adequacy of the service given in it and generally to give information regarding local views and wishes. The Provisional

Central Council's letter outlined what services in its district should be found in a hospital region when normal speaking should be based upon one central or hospital. Members of the Provisional Central Council are willing to attend meetings in the various regions of the British Hospitals Association and discuss with representatives of the voluntary hospitals their difficulties and problems. The address is 12 Grosvenor Crescent, S.W. 1.

#### Bacteriological Investigation of Puerperal Sepsis

Sir Arthur MacNalty, Chief Medical Officer of the Ministry of Health, has issued a leaflet to medical officers of health on bacteriological investigation with reference to puerperal sepsis. He recalls that the Departmental Committee on Maternal Mortality was early impressed with the number of fatal cases of puerperal sepsis in which no source of infection had been traced. Hence the advisability of combining epidemiological and bacteriological investigation more often particularly with a view to defining the responsibility of throat carriers and to elucidating the part played by other possible infective agents in persons in contact with the patient. By agreement with the Medical Research Council investigations were made at a central laboratory over a period of two years and these confirm the importance of carriage of infection in the various forms of puerperal fever due to the *Streptococcus pyogenes*. Since administrative difficulties often arise from bacteriological uncertainty regarding the nature and source of puerperal infections medical officers of health are asked to take every opportunity to obtain help on these points from bacteriologists attached to adequately equipped local laboratories.

On the occurrence of pyrexia in a young woman appropriate measures for the isolation of the patient should be arranged immediately. Steps should at once be taken to ascertain the cause of the pyrexia and where this is found to be due or suspected to be due to uterine infection, swabs should be taken from the cervix, throat and nose. Similar research should be made for any possible source of the infection—for example, one throat tonsillitis, laryngitis, anal or skin infection—in the persons who conducted the labour or were otherwise in contact with the patient during the subsequent forty-eight hours. Swabs from throat and nose and from any obviously infected site should be taken from all contacts, whether or not associated with clinical manifestations of disease. It should be remembered that in contact with patients and instruments is the most likely mode of infection of the genital tract; particular attention should be directed to infections or abrasions of the skin in anyone who has had such contact with the patient. Ordinary diphtheria swabs should be used for taking specimens except from the cervix, where a longer swab mounted on malleable aluminium is preferable. In swabbing the cervix a speculum should be used. The examination of the swabs may lead to the detection of the same bacteriological strain in a patient and in someone who has been in contact with her or to trace and remove the identity of the strain from the cervix with that from the throat or nose of the patient herself. As a result appropriate treatment can be applied and necessary disinfectant action taken to prevent further spread of the infection.

#### 'Family Meals and Catering'

The Children's Minimum Council gave a luncheon on March 30 at the London School of Economics. The menu was based on recipes from the British Medical Association's cookery booklet, *Full Time's a Cookery*, and the cost per head for the 20 guests was 5s. 6d. The meal consisted of soup and onions, a potato salad or mince with rice and vegetables or salad, a fruit cake and mashed potatoes, stewed fruit and custard or plum duff and bread and butter. Soup and onions followed by plum duff seemed to be the most popular combination. Lord Horder, who presided, said that he had just been informed by Sir Ralph Le Fleming that the copies of *Full Time's a Cookery* had been ordered to be

it was ever advertised, and a new edition would shortly be available. In his opinion, the problem of feeding the individual would only be solved by tackling the larger problems of food production and food distribution. Mrs Yates, wife of an unemployed labourer, said she could not even give her family the minimum laid down by the British Medical Association. Her total weekly income was thirty-eight shillings, of which more than sixteen shillings was paid in rent. Only ten shillings a week could be spent on food for herself, her husband, and her child. Miss Eleanor Rathbone, M.P., who is chairman of the Children's Minimum Council, also spoke, and concluded by saying that although the expenditure of the Children's Minimum Council was only £600 a year its funds were nearly exhausted. Unless additional financial support was forthcoming it could not carry on its work for more than a few months.

### Maternity and Child Welfare

A National Conference on Maternity and Child Welfare, organized on behalf of the National Council for Maternity and Child Welfare by the National Association of Maternity and Child Welfare Centres, will be held in the Great Hall of the University of Bristol on July 5, 6, and 7. The general subject of the conference, the president of which will be the Parliamentary Secretary to the Minister of Health, Mr R. H. Bernays, will be "The Child of the Future" and the discussions will be arranged as follows: psychology of pregnancy, in conjunction with the falling birth rate—its effect on the future, the need for closer co-operation between the school medical and maternity and child welfare services, and the need for increased provision of convalescent residential accommodation for children under school age, physical fitness in young children—(a) prevention of postural defects, (b) treatment of minor orthopaedic defects, the place of the voluntary worker in the schemes of local authorities, the parents of the future—(a) parentcraft teaching for senior scholars (boys and girls), (b) simple sex teaching in boys' and girls clubs, (c) individual preparation for marriage, and twenty years of child welfare—retrospect and prospect. The conference is open to all who are interested in maternity and child welfare. The fees for full membership, including the receipt of printed matter, are £1 1s per member. In the case of two members representing the same local authority or voluntary organization it will be 15s each, or in the case of three or more such members 14s each. Applications for tickets, with remittances should be sent to Dr Minett, honorary secretary, National Association of Maternity and Child Welfare Centres, 117, Piccadilly, W 1.

## SCOTLAND

### University of Aberdeen

Among other recipients of the LL.D. degree at the graduation ceremony of Aberdeen University on March 30 were two members of the medical profession, Dr E. J. Butler, F.R.S., Secretary to the Agricultural Research Council, and Dr Gunnar Dahlberg, Director of the Institute of Medical Genetics at Uppsala, Sweden. Professor T. M. Taylor, in presenting the recipients, said that Dr Butler had worked for nineteen years in India as Imperial Mycologist and Agricultural Adviser to the Government, and on his retirement from that post had been appointed Director of the Imperial Mycological Institute, while his experience had recently received further recognition by his appointment as secretary to the Agricultural Research Council. Dr Dahlberg was the leader of a new Scandinavian school of human genetics, who had made contributions to the mathematical analysis of human pedigrees with the object of distinguishing between the action of genes and the influences of environment. He was without doubt the leading human geneticist of the present day.

### Scottish Committee on Nursing

The inquiry into the recruitment and terms and conditions of service of nurses in Scotland was carried a stage further when the Departmental Committee on Nursing at their fifth meeting heard witnesses from eight more bodies. These bodies were the Scottish National Health Visitors Association, the South-Eastern Counties Joint Sanatorium Board, the Royal Samaritan Hospital for Women, the National Association of Local Government Officers, Edinburgh Royal Infirmary, Lanark County Council, Glasgow Western Infirmary and the Royal College of Surgeons of Edinburgh.

### National Institution for Mental Defectives

At the annual meeting of the Royal Scottish National Institution for the care and treatment of the mentally defective at Larbert, held in Edinburgh, Dr T. R. C. Spence, medical superintendent of the institution, said that many wild ideas were held regarding the part played by heredity in the cause of mental defect, but in fact we did not yet know anything about the transmission of defect. A defective child could appear in the midst of a normal family, and an even more striking fact was that the parents of mentally defective children were comparatively rarely themselves mentally defective. In this institution in practice not more than 5 per cent of the patients were found to have a parent who could be said to be mentally defective. The defective was a mental cripple and an innocent victim of misfortune. He was happier and more useful among those who were affected like himself, and he should be given a chance to develop his limited capacities to their utmost under sheltered conditions of life. It was stated at the meeting that the number of cases on the register of the institution was 732. The city of Edinburgh provided for mental defectives by four special schools capable of teaching 400 pupils, and had also an occupation centre with eighty pupils. The institution at Gogarburn had recently been enlarged by fifty beds.

### Massage for Fitness

An extension of the Scottish Clinic and School for Massage and Electrotherapy was opened in Glasgow on March 25. This clinic was founded in 1928, and the number of treatments has increased from 8,562 in 1930 to 42,480 last year. The clinic provides physical therapy for people unable to pay and whom the infirmaries are unable to treat. There is also provision for the practical training of students from the Anderson College of Medicine. Patients are attended only on the recommendation of their own medical attendant, and over 250 doctors regularly send patients to the clinic. Much of the treatment is carried out in the evenings so that patients are able to continue their ordinary employment during the day.

### Edinburgh Maternity Hospital

At the annual meeting of the Simpson Memorial Maternity Hospital it was stated that every effort would be made to have the new maternity hospital ready by October 1, although it was feared that the opening day might be nearer January 1 next year. During the summer the new building in the grounds of the Royal Infirmary would be open for inspection. The annual report shows that during 1937 the number of cases treated was 3,460, while attendances at the ante-natal and other clinics numbered 16,813. The maternal mortality during the year was 8.1 per 1,000 patients treated in the hospital, a decrease of 2.3 as compared with the figure for 1936. Most of these cases were emergency or difficult cases. The report refers to the likely effect of the Maternity Services (Scotland) Act 1937, which may diminish the number of outdoor cases available for the training of pupil midwives and medical students, and which will also involve increased expenditure in the appointment of a number of additional trained midwives at the hospital.

## Correspondence

### Modern Views on Pellagra

SIR—We wish to comment upon several points raised in your interesting leading article<sup>1</sup> under this title and to supply certain information not contained therein.

1 You refer to the results of Elvehjem et al. in treating canine black tongue successfully with nicotinic acid and await confirmation of their findings: this is now forthcoming. We had independently isolated nicotinic acid amide from aqueous extracts of liver before the appearance of Elvehjem's report and have since confirmed the observation that nicotinic acid will cure black tongue.<sup>2</sup> Similar confirmation has been made by at least three other groups of workers in this country.<sup>3</sup>

2 In referring to animal tests of fractions from yeast liver etc., for pellagra preventive activity you suggest that the application of results obtained from tests upon rats and dogs to human pellagra is difficult and uncertain. A distinction should be made here between tests with these two species. It was shown two years ago<sup>4</sup> by one of us that the rat deficiency disease then supposed to be analogous to human pellagra is in fact aetiologicaly different from the human disease and we have recently demonstrated that so-called rat pellagra is not cured by nicotinic acid<sup>5</sup> whereas four groups of workers have now found this substance to be active in curing human pellagra. The canine disease but not the rat disease, therefore resembles human pellagra in that treatment with nicotinic acid is curative. Moreover, throughout the long series of investigations conducted by officers of the U.S. Public Health Service it has consistently been found that foods and preparations active in the prevention or cure of black tongue are also active in the prevention or cure of human pellagra and materials inactive in the one disease are also inactive in the other. This parallelism between the materials which will cure each of the two diseases—extending right to the pure synthetic nicotinic acid—suggests strongly that black tongue and human pellagra are caused by deficiency of one and the same substance. From these considerations we conclude that the results of tests involving the so-called rat pellagra cannot be applied to human pellagra problems at all while the results of canine black tongue tests can be applied with much confidence.

3 The question is raised in your article whether the consumption of trigonelline contained in the bread eaten in rural Lower Egypt has any influence on the incidence of pellagra. We have isolated trigonelline from liver extracts in addition to nicotinic acid amide and have tested its activity in canine black tongue. Six dogs each of about 10 kg weight were given a slightly modified Goldberger No 123 diet<sup>6</sup> and watched until they developed black tongue as judged by inflammation of the mucous membranes of the mouth and throat, loss of weight, excessive salivation, loss of appetite, listlessness, and diarrhoea. As each developed black tongue it was treated parenterally with trigonelline. One animal received a single dose of 120 mg and the others received daily doses of 10, 20 or 40 mg. All the dogs showed increasingly severe symptoms and died within four days after treatment was begun. Controls were provided by other dogs which were allowed to develop black tongue and were then treated with doses of nicotinic acid of the same order as the trigonelline doses. These dogs soon regained their appetites, increased in weight and their

mouths returned to normal. It appears from this observation that trigonelline has no curative power in black tongue and it can be confidently predicted that it will have no curative or preventive power in human pellagra. It has long been known that the dog excretes a part of the nicotinic acid fed to it as trigonelline<sup>7</sup> whether the transformation is a detoxication mechanism for dealing with excessive amounts of nicotinic acid or whether it occurs during the normal processes into which nicotinic acid enters is not known.

You also raise the question of the complication of the current position introduced by Leutsky with his observations on pellagra like lesions in mice.<sup>8</sup> It is probable that this work can at present be dismissed from consideration in this connexion as no evidence that the mouse syndrome is identical with human pellagra has been adduced. When Goldberger first produced a symmetrical dermatitis in rats by means of a dietary deficiency twelve years ago it was reasonable to regard it as analogous to human pellagra but it has since been abundantly proved that the analogy is superficial. In more recent years a dermatitis of chickens has been regarded as rat pellagra. This disease again is really not analogous to human pellagra as it is not cured or prevented by the same materials. Jukes has shown that the factor responsible for cure of the chick disease and human pellagra respectively are differently distributed in natural foodstuffs and we have shown that nicotinic acid will not cure the chick disease.<sup>9</sup> In view of these earlier experiences with pellagra like diseases caution should be observed in calling any animal syndrome pellagra until it has been shown (a) that it can be produced on the deficient diets upon which human beings develop pellagra, (b) that a number of foodstuffs (or one chemical pure substance) known to prevent or cure human pellagra will also prevent or cure the animal disease and (c) if one of the symptoms is a dermatitis it must be shown that the appearance of the dermatitis is dependent upon exposure to light following a period of refeeding on the deficient diet. Leutsky has not established any of these criteria for the mouse condition which he describes. Applying these criteria canine black tongue and the recent described disease in pigs<sup>10</sup> are the only true analogues of human pellagra which we know to-day.—We are etc.

### Causation of Cancer

SIR—Dr W E Gye's lecture, published in the *Journal* of March 12 (p 551), is an admirable summary of the present position of experimental cancer research, but it is regrettable that in the words of the old music hall song "he cannot see the fields for the houses in between." Dr Gye appears to object to the theory that tumour formation is due to the mutation of genes in somatic cells, not because he can bring forward any facts which disprove it, but because of the means by which this theory has been arrived at. The theory was admittedly formulated by a process of logical deduction, but apart from the argument that if we can arrive at the truth how we get there is a matter of but small importance, the method of logical deduction is often the best way of advancing our knowledge of obscure phenomena, more especially when they involve structures too small to be visible even with the aid of the most efficient microscopes.

In dealing with such problems there are two well-recognized means of investigation open to us: first, by experiment, and, secondly, by deduction from analogy and seeing whether deduced consequences actually occur. Dr Gye is a brilliant exponent of the first method, but it is a pity that he should try to ridicule the second, which in other fields of science, such as astronomy, has given such wonderful results. Most of our present knowledge of the universe has been built up by such methods, and to say that they are unprofitable in advancing our knowledge of things that cannot be directly observed does not seem warranted by the facts. His statement that the somatic mutation theory, even if correct, "offers no prospect of further advance in knowledge" is a curious one to be put forward by a scientist. I have always believed that science is the pursuit of knowledge for its own sake, and that the true scientist is not concerned with the results that may accrue, and which in any event are quite incalculable. Could Newton or Volta have had any idea of the results to which their discoveries would ultimately lead? I am convinced that the somatic mutation theory will prove to be the true explanation of the change occurring in a normal cell which results in malignancy. No facts which disprove this have yet been brought forward, nor does Dr Gye offer any—I am, etc.,

J P LOCKHART-MUMMERY

### Results of Radiotherapy

SIR—From the letters on radiotherapy which have recently appeared in your columns, a few points emerge which appear to me to need emphasis. One of your correspondents infers that radiotherapy merely converts a painless disease into a painful one. Another quotes excellent results in similar cases but achieved without pain. Now any doctor who has watched his patients die of cancer knows how painful death can be apart from treatment, whereas severe pain caused by radiotherapy is not often seen in expert hands.

It is surely as unreasonable to judge radiotherapy by its worst results as it would have been to judge surgery in its early days. Many operations have now been proved to be useful although at first they were associated with much pain and a high mortality. It seems to me impossible for anyone, however critical, who takes the trouble to visit a few of the chief centres at home and abroad not to be deeply impressed by the remarkable results obtained by leading exponents, and often with little or no discomfort to the patient.

The fact is that at the present time there is a dearth of first-rate radiotherapists. The need for continued research has already been emphasized, but this comparatively new field of enormous promise is not attracting enough of the best type of men. The reasons are various, and include the question of status as well as finance, but until these difficulties are faced and solved there will remain this great discrepancy between the results of radiotherapy obtained at different centres—I am, etc.,

London, W 1, April 5

REGINALD HILTON

### The Mechanism of the New Chemotherapy

SIR—Your leading article on this subject (March 5, p 522) was, I think, unintentionally misleading on one point—a point of some importance. Referring to Levaditi's hypothesis that both red prontosil and sulphanilamide are changed in the body into some more active substance you say, quite rightly, that this was based upon the "fact that the drug is ineffectual in experimental intraperitoneal infections if given by the same route. It saves life only when given by the mouth or parenterally." A recent experiment of my own seems to show clearly that this is not the case, mice can be readily saved by the drug if it is administered intraperitoneally in repeated doses. (It appears from Levaditi's paper<sup>1</sup> that he gave only a single dose.)

*Experiment*—A culture of streptococcus (about 100 mld) was injected into the peritoneum of ten mice. Two hours later sulphanilamide (10 mg) was given by the same route to five of them and subsequent doses (7.5 mg) at ten, twenty-four, forty-eight, and seventy-two hours. The five untreated animals died within thirty-six hours. The treated mice were never very ill, soon recovered, and survived in good condition for twenty-one days, when they were killed. No haemolytic streptococci were recovered from their spleens or peritoneum.

In the light of this result one may well hesitate to accept Levaditi's conclusion without further evidence.

May I make one other slight correction? You state that Trefouel, Nitti, and Bovet "asserted" that red prontosil "is broken down in the body" into sulphanilamide. Actually these authors—to whom all honour is due since we owe to them the introduction of sulphanilamide and many other contributions to this new chemotherapy—only suggested the *probability* of this breakdown of prontosil into sulphanilamide. It was my colleague, Dr Fuller,<sup>2</sup> who brought forward the evidence that it did occur.

In conclusion I entirely agree with you that at the present time the experimental data at our disposal do not warrant any final conclusion as to how red prontosil and sulphanilamide exert their curative effects—I am, etc.,

London, W 6 April 1

LEONARD COLEBROOK

SIR—The medical profession all over the world is to day under the impression that all kinds of streptococcal infections can be cured by prontosil and its derivatives. Experiments in mice and clinical reports agree on this point, but the mechanism of its action has not been determined as yet, the effect is attributed to a certain bacteriostatic action. For the last two years my work has been chiefly an attempt to determine (1) other forms of its action than the bacteriostatic effect, (2) why certain cases do

<sup>1</sup> *Monographies de l'Institut Alfred Fournier* No 5, Paris, 1917

<sup>2</sup> *Lancet*, 1937, 1, 194

not respond to sulphamylamide in spite of large doses and (3) what other factors assist in the success of sulphamylamide therapy.

When, in collaboration with Dr Eva Stuge-Schreiber I synthesized a highly soluble sulphamylamide compound I found the following: (1) Sulphamylamide has a direct action on the body of the bacterium and destroys its structure. (2) In the test tube growth of streptococci in blood of sulphamylamide treated patients is inhibited in protiosol broth growth is not inhibited merely the virulence is attenuated and the toxin production inhibited. (3) Sulphamylamide inhibits the formation of toxin in the organism. (4) Sulphamylamide does not neutralize already present toxins. Consequently we can say that: (1) in the mouse sulphamylamide is highly effective against infection with small doses of strongly virulent streptococci. (2) Sulphamylamide exerts a weaker action against infection with large doses of less virulent strains. (3) It has little effect against streptococcal infections in guinea pigs induced by infection with highly toxic full cultures. (4) Also in these animals sulphamylamide is highly effective in combination with antitoxic streptococcal serum.

Applying these experimental experiences to severe cases of human streptococcal infections with already existing intoxication (as for instance puerperal fever) I observed the following: (1) Sulphamylamide acts only in organisms which possess a certain natural resistance. Therefore its action can only be explained as a co-operation of drug and organism. (2) Cases which do not respond to sulphamylamide may be cured by additional treatment with antitoxic streptococcus serum. The same holds true for cases not responding to serum treatment which may recover by adding sulphamylamide. (3) Inasmuch as the chemotherapeutic agent can only exert its action under co-operation of the natural defence system of the infected organism, this resistance must be supported by all possible means (immune transfusions, vitamins, etc.).

The toxic by effects of sulphamylamide can be avoided by combining serum and sulphamylamide because this combination makes the reduction of the sulphamylamide dosage below the point of danger possible. Since I feel that the combination of two good therapies into a perfect one—instead of substituting one for the other—is a very important factor in our fight against puerperal fever and all other forms of streptococcal septicaemia I should appreciate your bringing this letter to the attention of the medical profession—I am, etc.,

New York March 21

FRITZ MEYER M.D.,  
Prof. Dr. Med.

### "Gonococcus Antitoxin" for Gonorrhoea

SIR—Dr T. Anwyl-Davies (*Journal* March 26 p. 701) seems to forget that what he calls adjuvant treatment is the recognized official and orthodox cure. So that when he says that "at the present time irrigations, dilatation, prostatic massage, etc. are also carried out," he means in effect that patients are subjected to two entirely different types of treatment or cures simultaneously—the orthodox and the specific antitoxin treatment. His comparison of the orthodox treatment of gonorrhoea with the treatment of diphtheria has already been adequately dealt with by me (*February 20 1937 p. 415*) and by E. T. Burke and others (*April 2 1938 p. 755*).

However the important point is that Dr Davies by his dismissal of the orthodox cure as simply adjuvant treatment has failed in the very crux of the matter—the critical comparison of the two treatments or cures.

In his reply to my first letter Dr Davies (March 6 1937 p. 721) admitted that "some of the cases quoted had no other treatment, others were treated along routine lines." This is the way in which my criticism was read and answered. No attempt was made at a critical and detailed comparative analysis nor was any mention made when of its being inadvertently omitted. Therefore I submit that when a confession that irrigations, dilatation, prostatic massage, etc. are also carried out with the end in view although in my preliminary paper this procedure was inadvertently omitted from the text is made Dr Davies's technique is made manifest in all its inadequacy. How can the very kernel of a clinical investigation—that is the evaluation of new methods as against the old—be omitted and disposed of by declaring that the controls were inadvertently omitted. One can pass over the absence of detail but never the absence of essentials. The absence of essentials denotes in my opinion the absence of method and herein lies probably part answer to the discrepancy in the results found by Dr Davies with those recorded by E. T. Burke and the three other investigators (March 19 p. 605)—I am, etc.

Enfield April 2

W. LESTER.

### Treatment of Burns and Scalds

SIR—In the excellent paper on the treatment of burns and scalds by Mr Philip H. Mitchiner (*Journal* January 1, p. 27) a typographical error appears in the paragraph on silver nitrate. I believe the author was quoting from my paper in the *Archives of Surgery* (1937 35 475). He states:

The patient having been given a dose of sedative and the area of the burn being cleaned as already described, the tannic acid treatment the whole of the burn area is painted or sprayed once with a 1 per cent aqueous solution of gentian violet and is thoroughly scrubbed over with a 10 to 15 per cent solution of silver nitrate care being taken that the silver nitrate does not escape over the surrounding skin. The area is now again sprayed or painted with a 10 per cent solution of gentian violet.

This last sentence should read: "with a 1 per cent solution of gentian violet."

One other statement which is somewhat misleading is from the use of this method the American author reports a mortality of 73 per cent. This is considerably higher than that from weak tannic acid solution as might be expected when one realizes that in the case of extensive burns the silver nitrate coagulum does not extend into the deeper damaged tissues. In my article the mortality rate of 73 per cent was based on the treatment of ninety-five patients during the experimental period in which we were changing over from tannic acid to the combination of silver nitrate and gentian violet and working out a new technique. When the hospital routine has been properly worked out the next eighteen patients required admission were treated on the same tannic acid treatment with no deaths. The statement made by Mr Mitchiner that the silver nitrate coagulum does not extend into the deeper damaged tissues explains why tannic acid is rarely if ever necessary with modern combination treatment. Tannic acid cannot be soaked out of the skin as can the silver nitrate-gentian violet coagulum. Thus the removal of the tannic acid does not so help the patient as lands which is left with spread and increased infection grafting unnecessary—I am, etc.

Dr. R. M. C. 19

HENRY E. BUCKLEY

### Treatment of Boils and Carbuncles

SIR—Mr J Hosford, in his article in the *Journal* of February 19 (p 400) on the treatment of boils and carbuncles, mentions a great variety of treatments, including short-wave diathermy. He does not mention infra-red irradiation, which gives excellent results in the treatment of carbuncles and has a marked analgesic effect. Nearly all practitioners using electrotherapy possess some sort of infra-red ray apparatus, which is therefore more easily available for the treatment of boils and carbuncles than the costly and complicated short-wave diathermy machines, which are not standardized as yet. The following case may illustrate the value of infra-red irradiation in the treatment of a large carbuncle.

A man aged 58 was seen on November 17, 1937, with a large carbuncle on the back of his neck. He had no glycosuria. I started to treat him with infra-red irradiation on the same day. He received daily administrations of forty to forty-five minutes each. No other treatment was given, except that the skin around the carbuncle was cleaned with ether before treatment and ung. hydrarg. ammon. dil. was applied round it after the treatment, and covered with a light pad of gauze and cotton-wool. The patient felt immediate relief after the first treatment and his neck movements were more free. The discharge became much thinner after two days' treatment and the core separated on November 25. The wound was almost completely closed on November 29. Considering that the carbuncle was about 3 inches in diameter, the final soft scar a quarter of an inch in diameter represents a good cosmetic result.

I have treated during the last twelve months two other carbuncles, including one facial one, in the same way and with the same excellent results. I do think, therefore, that infra-red irradiation should occupy an important place in the treatment of boils and carbuncles. Its application is simple and not costly, and the results are quick and excellent—I am, etc.,

South Norwood, SE 25, March 27

A FREITAG

### Pasteurization of Milk

SIR—The letter of Dr Halliday Sutherland (March 26 p 704) is like a refreshing breeze in the stale atmosphere of the milk-spoilers. He makes eight points which may well rally the believers in fresh milk. The eighth is expressed as a suggestion that it would be wise to test the effects of pasteurization on the fertility vitamins. Like Sir Leonard Hill, he sees depopulation on the horizon. Pasteurization, he implies, would accelerate it. There is little doubt that the implication is right. The two experiments of E C V Mattick and J Golding at the National Institute for Research in Dairying at Reading University (*Lancet* 1931, 1, 662) revealed that rats receiving raw milk were in their fourth generation at the time of reporting and showed no falling off in their rate of growth, whereas none of the third generation of a precisely similar group fed on freshly sterilized milk lived for more than a day. In a third group receiving sterilized milk which had been kept in a cold cellar for twenty-four hours, none of the second generation lived to weaning. The matter is important. By all means let further experiments be made, as Dr Sutherland suggests—though it is hard on the rats!—I am, etc.,

Holmes Chapel, March 27

LIONEL J PICTON

SIR—Dr C O Hawthorne (April 2 p 753) has missed one point in my letter in the *Journal* of March 26 (p 704). Although pasteurization may not affect the nutritive value

of milk I suggested that it might affect the fertility vitamins. This point could be settled in a few months by feeding and breeding experiments on animals. Lady Lionel Guest in the *Daily Telegraph* of March 10 states that "cats and dogs, unless almost starving, refuse to drink pasteurized milk, even rats will not drink it willingly, and they are not famous epicures." If that be accurate the experiment might be tried on mice. As the population will soon be the most serious problem of our country I hope that someone will make the experiment on at least four generations of animals.

I regret that I misread Dr J Kirkland's letter, but I do not agree when he writes of "death dealing germs that cannot be removed from raw milk except by pasteurization" (April 2, p 754). The tubercle bacillus is absent from the milk of TT herds. Bang's disease (*Br. abortus*) can be eradicated from herds by the agglutination test and the slaughter of reacting animals. In America the Federal Government set up a scheme in 1934 whereby owners of reacting animals were compensated to the extent of fifty dollars each on pure-breds, and twenty-five dollars on grade cattle, provided the animals were immediately sent for slaughter.

As regards infection from human sources whereby both raw and pasteurized milk may be contaminated, this could be obviated, as Dr F R Brown (April 2 p 754) suggests, by the periodical medical examination of all dairy workers and those employed on pasteurization. Yet Dr Brown is in error when he states that a tuberculosis carrier could easily infect the cows as well as their milk. It implies that the cows would develop the disease. Dr Severi Savonen, Director of the Finnish Association for the Prevention of Tuberculosis, refers in the *Tuberkulösläbilet* of March, 1937, to a recent discovery by Dr R Stenius, veterinary surgeon. He found that healthy, tubercle-free cattle when experimentally infected with tubercle bacilli from human sources gave a positive tuberculin reaction without developing the disease. Moreover, he found several cases in which dairy cows had been thus infected by persons suffering from open pulmonary tuberculosis. The cow is thus infected by tubercle bacilli of the human type and reacts to the tuberculin test, but when the consumptive attendant, the source of infection, has been removed from the cowshed the animals lose this acquired sensitivity to tuberculin and cease to react to the test.

The milk of a cow infected from human sources contains no tubercle bacilli unless—and there lies the danger—the milk is subsequently contaminated by the consumptive who infected the cow. By a closer study of tuberculin reactions in cattle it is now possible to distinguish between infection from bovine and human sources. A list of all cattle whose reaction to tuberculin indicates infection from a human source is sent from the State Veterinary Department to the National Tuberculosis Association. Every farm where these reactions have occurred is visited by one of the district tuberculosis officers, who examines and x-rays everyone in contact with the cattle in order that the infectious consumptive may be discovered and removed for treatment. In Britain I had known of search being made to discover a particular cow whose milk had caused the death of children, but never before have I heard of a search to find the consumptive who infected cattle.

The best news about our milk supply is the recent announcement by the Scottish Milk Board that within the next five years the full needs of consumers in Scotland will be supplied from tubercle-free herds. There is no reason why this scheme should not be extended to England. Then all your readers will be able to drink fresh unpasteurized

milk, which possibly some of them have never tasted. Anyone can see the difference between rich fresh milk and the anæmic chalk white stuff in the bottles and any one blindfolded can taste the difference—I am etc.

London W 8 April 2

HOLIDAY SUTHERLAND

## Trauma and Progressive Muscular Atrophy

SIR—For the following reasons it appears unlikely at first that trauma plays any significant part in the aetiology of progressive muscular atrophy.

1 The fact that there is an age group (up to 25 years) in which females predominate, after this admittedly it occurs three times more frequently in males.

2. The fact that the bu bar type of the disease has not been reported to have followed injury—so far as I can ascertain

3 The probability, as emphasized by Dr G F Walker and Mr D Stanley Jones (*Journal* February 12 p 360) that the injury occurs as a result of the negative weakness and muscular cramps which often precede the onset of wasting and objective weakness and the further probability that most patients could recollect an injury of some kind preceding almost any illness.

However in the cases quoted by Dr G E Frederick Sutton (January 29 p 225) the injury would not fall into the last category. It was in every instance a severe injury which might well have caused a molecular disturbance of brain or cord. In such cases one would not necessarily expect any correlation between the site of the original injury and the site of onset of the atrophy. In the cases where such a correlation does exist two explanations are possible.

(d) Thieme's theory that a traumatic ceding neuritis ultimately affects the motor cells. The axonal spread of this instance anterior poliomyelitis might support this but Dr Sutton observes that symptoms of neuritis are conspicuous by their absence in his history of practically all the cases of post traumatic progressive muscular atrophy.

(h) The association may be coincidental and in this connection surely a statistical analysis of say 200 cases which would no doubt be possible at the National Hospital would reveal whether the incidence of conditions associated with or precedent to progressive muscular atrophy gave any significant prominence to injury. Association with previous anterior poliomyelitis is too well known and too pathologically probable to bear dispute but in the case of injury the incidence would have to be high to acquire significance. It would also be very informative to learn whether the bulbar type of disease has ever followed injury. If not why should it be exempt? The nature of the injury in the cases quoted would lead one to expect this type.

I recollect two cases of progressive muscular atrophy in a London ward at the same time one with a history of infantile paralysis and the other with a history of wrist drop due to lead poisoning. In both cases the limbs affected by progressive muscular atrophy were those affected by the previous lesion. Shortly afterwards I attended a necropsy on a case of progressive muscular atrophy which developed rapidly following exposure to a new industrial chemical the potential toxic properties of which were unknown. Here again coincidence has not yet been excluded.

Dr Sutton supports the view that trauma may render the motor cells susceptible to the subsequent attack of an unknown virus or toxin. If this is accepted the aetiological factors might be classified in some such way as the following:

The cells are rendered susceptible by (1) a hereditary predisposition (this might account for the early age group in

which females predominate) (2) trauma (3) previous infection—for example acute anterior poliomyelitis (4) previous infection—for example syphilis (5) previous intoxication—for example alcohol (6) previous infection—for example lead and (6) present intoxication. It is very likely that a number of these factors may be associated with one another and the possibility of which should be (and perhaps are being) investigated.

This still leaves the actual causative virus or toxin to be accounted for and would not explain why some cases associated with a positive Wassermann apparently recover after arrested with specific treatment unless in these cases the spirochaete is the final causative agent of the disease. I believe no pathological evidence—I am etc

## Sequelae of War Gas

SIR—The high mortality rate among ex-soldiers in certain age groups as compared with the corresponding statistics for civilians who had had no war service is referred to in the *Journal* of January 1 (p 21).

It is there stated that the mortality rates are from 75 per cent to over 70 per cent in excess of normal in different countries. It has been observed in New Zealand that the mortality statistics for respiratory diseases are 20 per cent above normal in similar groups of ex-servicemen. It was suggested by Mr H. Ramsbottom in the House of Commons debate on the matter that any type of pensioning Acts was impracticable. No such restriction is necessary. What is required is a wider agreement on the recent research work that has been done on the sequelae and its application to ex-servicemen and to those who have had an opportunity of acquiring their views with the clinical evidence.

The idea that all ex-soldiers with gas sequelae have persistent respiratory tract damage with symptoms suggestive of chronic bronchitis does not. Such sequelae are seen principally in those damaged by vesicant gas. Another fallacy is the general belief opinion that all soldiers who developed gas sequelae recovered and sufficient severe symptoms at the time to warrant evacuation as gas casualties. The only evidence of degenerative lung changes without previous exposure is also an unassociated and large unrecognized factor. Phosgene lesions of the alveolar septa have been shown to heart insufficiency often extending into the peripheral. Such cases have a high mortality rate from peripheral disease and will be found to be large factors in the high group mortality rate in question. Perhaps the departments the world over have been slow to appreciate and recognize the different types of gas lesions with the result that they have been outmoded by the most recent statistical developments.

The full extent of the lack of appreciation for this is well illustrated by a brochure recently published by the United States Chemical Warfare Service. On page 1 of the Army Chemical Warfare Service's "On Gas" it is stated that gas produces practically no permanent injuries so that if a man who is gassed survives he comes out better than as God made him. The incidence of fatal effects and civilian casualties among soldiers in the gas-impregnated group in New Zealand is so high that no other explanation is given. Auckland Hospital has come to realize that only the best films will accommodate the increased interest in gas.

### Sodium Lactate for Diabetic Coma

SIR,—I have read with interest your annotation in the *Journal* of March 26 (p 683) concerning the treatment of diabetic coma by the use of racemic sodium lactate.

I should like to point out the following error. Referring to Hartmann's article in the *Archives of Internal Medicine* September, 1935, you stated that the third group was treated by 'insulin, glucose, and racemic sodium lactate'. No glucose was given. This was shown in Table I and Chart 3 of the above article. In another of Hartmann's articles (*J. clin. Invest.* 11, No 2) he states "that the conversion of lactate into glucose is apparent from the uniform rise of the latter in the blood". His treatment of diabetic coma or acidosis is as follows:

10 ccm of molar sodium lactate per kilo body weight	
50 ccm of distilled water	
40 ccm of Ringer's solution	
2 units of insulin	

About 1/3 to 1/2 of the above fluid is given intravenously and the remainder subcutaneously or intraperitoneally.

In view of the suggestion as to the meagre possibility of harmful effects from the administration of sodium lactate, I should like to refer to the thirty cases published in the above journal. I have had three years of personal experience with this form of treatment at the St. Louis Children's Hospital, and the results have been extremely satisfactory. A paper giving details of about sixty cases of diabetic acidosis in which this treatment was instituted is soon to be published; no harmful effects were noted from the administration of sodium lactate. In addition to these, Hartmann has also obtained excellent results with the use of sodium lactate in acidosis due to nephritis, diarrhoea, dehydration, infection and many other miscellaneous causes such as salicylate poisoning etc.—I am, etc.,

JACK BASMAN

### Plantar Warts

SIR—The frequency with which the treatment of plantar warts is discussed indicates the difficulty of successful therapy. I write to make a strong plea for surgical treatment by means of the high-frequency electrical current. By such means it is possible to excise warty tissue and surrounding structures and to coagulate and fulgurate the exposed basal area. Small isolated warts can be successfully treated by this method under a local anaesthetic. Novocain 2 per cent, should be injected through a wide needle and the tissue surrounding the base of the warty lesions deeply infiltrated. This will give satisfactory anaesthesia and avoid the difficulties and pain which follow attempts to anaesthetize locally the base of the wart. Larger warty areas are best treated under a general anaesthetic. The previous failure of radium rays, chemical agents and surgical excision makes treatment difficult and causes prolonged disability.

The disadvantage of treatment by high-frequency electrical currents is the long time required for healing of the exposed area. Usually it takes five to seven weeks. High frequency treatment prevents haemorrhage, however, and lessens the risk of infection spreading through the lymphatic and capillary vessels. Healing can be accelerated by exposure to ultra-violet rays. Two days after the warty area has been excised and the basal area coagulated and fulgurated by the electrical current the area is exposed to the rays of the quartz mercury vapour lamp and five normal skin erythema doses are applied. Local irradiation

augments the blood supply, hastens the formation and separation of sloughs, accelerates the formation of granulation tissue, and stimulates healing; it also keeps the wound clean and sterile. Such local treatment is applied at intervals of two to three days until healing is completed. The treatment does not produce much 'after pain' and often patients can be allowed to get up and walk. As a precaution to prevent reinfection of warts I prescribe lin. pot. iod. saponis (B.P.C.) to be rubbed into the skin of the sole of the foot daily—I am, etc.,

— London, W, March 29

ALBERT EIDINOW

### Multiplicity of Special Diplomas

SIR,—A letter from a correspondent signing himself "H. M." appeared in the *Journal* of March 26 (p 704). The letter dealt in general with the inadvisability of multiplying special diplomas in medicine, and the particular association which I represent was especially singled out for attack. We were, however, honoured by being placed in the dock in the company of the British College of Obstetricians and Gynaecologists. Personally, I am in agreement with "H. M.'s" general thesis, but this agreement is purely theoretical. Those concerned with the progress of a particular specialty must take the world as they find it. So long as special diplomas exist which are obtainable by examination, and so long as the profession and the public attach importance to these diplomas, it is incumbent upon any body of men who wish to raise and maintain a particular professional standard to see to it that their examinations compare favourably with those of other bodies. In his argument that examinations are useless "H. M." proves too much, because such a criticism must obviously apply equally to the qualifying degree of which he has apparently such a high opinion. What ever the disadvantages of examinations, no one has yet invented a satisfactory substitute. Examinations in medical subjects are certainly not of recent origin. Very stiff examinations were conducted at the various medical schools in the Middle Ages.

Your correspondent gibes at the original Fellows of both the College of Obstetricians and the British Association of Radiologists. In the case of the latter, foundation fellowships were awarded only to those who had already held the highest offices in the gift of their radiological colleagues, and it could scarcely be said that possession of the fellowship is of personal advantage to them. Your correspondent says that the Association 'sets itself up to re-examine those who already possess a recognized diploma in radiology'. It is necessary to explain that the diplomas in radiology obtainable in this country are awarded after a nine months course of study open to any registered medical practitioner, so that they may be obtained within a year of graduation. These diplomas have fulfilled, and still fulfil, a useful purpose. Twenty years ago it was perhaps possible to acquire a fairly accurate knowledge of radiology, both diagnostic and therapeutic, in nine months. To-day both these subjects have so expanded that it is possible to acquire a ground-work only in such a limited time. Nevertheless it is a fact that many of the smaller centres throughout the country will be permanently unable to support a radiological specialist in each branch of radiology, and the existence of diplomas combining the two will continue to secure that men do not set up in practice in these important lines of work without adequate grounding. When it comes to what we may call the higher walks of radiology such dualism is now rarely practicable. There-

must be specialists in both radiodiagnosis and radiotherapeutics and it is to secure the proper training and certification of such specialists that the Fellowship of the British Association of Radiologists has been instituted. The possession of a diploma is insisted upon because the two years work demanded by the Fellowship is supposed to start where the diploma leaves off. Moreover the examination includes general medicine and surgery and pathology in their special relation to radiology and the Association has been fortunate in securing the services of eminent persons as external examiners. The suggestion therefore that the Association sets itself up to re-examine persons who have already passed an examination of the same standard is an entirely false one. It must be remembered that undergraduate teaching of radiology has so far been negligible. The groundwork which is laid down in for example surgery at a medical school must be laid down in the postgraduate period so far as radiology is concerned.

H. M. says that British medicine alone seems to find a multiplicity of special diplomas necessary. Perhaps he is right as regards the Continent but America appears to be following our example as fast as possible. Within the last decade or so there have been instituted an F.A.C.P., F.A.C.S. and F.A.C.R. In addition to these an American Board of Radiology conducts an examination for a diploma which is obtainable only by those who have done five years approved work after medical graduation. I would point out that this is exactly the total period of approved work after graduation demanded by the F.B.A.R. There are also in America boards of neurology, orthopaedics and other special subjects. Whether or not any of these boards have yet instituted diplomas I do not know but I venture to think it is highly probable that they will do so. In short whether the tendency be good or bad it is one which permeates the whole English speaking world including the British Dominions.

Finally your correspondent seems to feel it a grievance that special diplomas are usually required for important appointments. He should not however mix up the sequence of cause and effect. It is the governors of these institutions who decide that candidates must have certain diplomas and they do so apart from any influence which may be brought to bear upon them by the examining bodies concerned—I am etc.

### Pneumonitis

SIR—I was most interested in Dr A. Morton Gill's paper on pneumonitis in the *Journal* of March 5 (p. 204). That pneumonia occurs in forms which differ widely from the classical descriptions of the disease has been known to all of us for some time. There is no doubt that many of these anomalous forms can be split into well defined clinical and radiological entities and it is surely time that we ceased classifying under the term pneumonia illnesses differing widely in their course and final outcome. Credit must therefore be given to Dr Gill for his admirable description of the clinical and radiological entity to which the name pneumonitis may be given. Dr J. G. Scadding too should be congratulated on his definition of chronic diffuse bronchopneumonia and disseminated focal pneumonia (*Journal* November 13 1937 p. 926). One more scrap heap which has encumbered the progress of medicine is being removed.

Exception must be taken to Dr G. S. Erwin's letter in your issue of March 26 (p. 703). He gives as his address the Brompton Hospital and therefore it might be thought that his opinions carry an especial weight. Actually however he chooses several very minor points in Dr Gill's paper and subjects them to rather nebulous scrutiny. Nevertheless it is criticism such as this written once in a while in a rather carping spirit which can do a great deal of damage to an excellent piece of work. It is to be noted that Dr Erwin has no objections worth offering to the general substance of Dr Gill's paper.

The following are the details of a case of pneumonitis recently seen in the out-patient department of the Hospital for Sick Children Great Ormond Street. I am indebted to Dr Lightwood for permission to record in this case.

A female infant aged 14 months was seen at the beginning of December 1937 with a history of an irritating cough for the previous two weeks. There had been no fever and the child had never been confined to bed. On examination she was a healthy looking child with no respiratory abnormality. Her weight was 20 lb and the rectal temperature was 99° F. The chest showed some dullness at the left base where breath sounds were weak and there were some crackles. Examination of the other systems revealed nothing abnormal. The Mantoux test (1 in 1000) was negative. A radiograph of her chest taken at this time showed marked shadowing at the left base. A simple linctus was prescribed. When seen again a week later the mother said the child was very much better. One week after this the abnormal physical signs had cleared and a second radiograph showed that the opacity had completely disappeared. The child did not cough and gained weight rapidly.

The points which I would emphasize are: First the fact that there was never any question during the whole of the illness of admitting this child to hospital. She was treated quite satisfactorily as an out-patient. Second though a 1 in 1000 Mantoux test only was done yet this coupled with the rapid subsidence of the condition in my opinion definitely rules out any question of tuberculosis—I am etc.

London SW18 March 28 C. HARDWICK M.R.C.P.

SIR—I was most interested to read the admirable paper on pneumonitis by Dr A. Morton Gill. That condition exists as a clinical entity in children in my opinion cannot be disputed by anyone who has had experience in paediatrics. In adults the condition would appear to be a rare one. The following report may be of interest therefore.

On February 10 I was called to see a female diabetic aged 55 who was complaining of cough and exhaustion. On examination she had a temperature of 99° F, a pulse rate of 90 and a respiration rate of 20 with some rales in the periphery. There was impairment of the percussion note at the base of the right lung but the breath sounds were normal. Many rales were heard. She was put to bed and given medicine to control the cough. On the following day she had a severe haemoptysis. Evening physiotherapy continued for 3 days and then subsided. At the end of the first ten days signs were much less marked. Fourteen days after the onset she was quite free of all signs and symptoms. During the illness her only requirements in food were 100 g of food to 20 units daily but returned to her normal diet. No tubercle bacilli were found in her sputum. She remains well.

The association of malaise, cough, evening pyrexia and haemoptysis strongly suggests tuberculosis in a patient of this type. However the complete and rapid recovery has led me to conclude that this was a case of acute pneumonitis—I am etc.

D. C. REAVEL, M.D.

### Aetiology of Acute Appendicitis

SIR—In an article by Dr A M Spencer in the *Journal* of January 29 (p 227) it is stated that in the villages of India appendicitis is unknown. I am a beginner at surgery, but I can select from my records of civil surgical practice twenty eight cases of appendicitis proved at operation in persons from Indian villages and small country towns. All the appendices were pathological some were removed with difficulty owing to old standing adhesions others were perforated. All the patients were persons living on purely Indian dietaries and some were vegetarians. I have excluded cases of appendicular abscesses and cases occurring in those natives partial to European foods—I am, etc,

Coorg South India March 16

R D MACRAE  
Captain I.M.S.

SIR,—Dr A M Spencer in his paper on the aetiology of acute appendicitis in the *Journal* of January 29 (p 227) states that acute appendicitis is very common among the inhabitants of Tristan da Cunha. He also states that the diet of the inhabitants has an exceptionally low cellulose content. I have visited Tristan da Cunha twice and have made an examination of the inhabitants for H.M. Office of the Crown Colonies. From information obtained in the island it is very unusual for anyone to have symptoms suggesting acute appendicitis. When such symptoms do occur the only treatment that can be given is a dose of castor oil or Epsom salts. I was unable to obtain any facts regarding a death suggesting a perforated appendix.

As Tristan da Cunha has never had a resident physician a true diagnosis of any illness has never been obtained, so Dr Spencer's statement is made without proof. Regarding the diet the staple article is potatoes. Fish is plentiful, and during the nesting season penguin and albatross eggs are obtained in great numbers. Turnips, carrots, and cabbage are to be had but are not plentiful—I am, etc,

E F D OWEN  
RMS *Empress of Australia* at Sea March 22

### Chronic Litrtritis

SIR—In the *Journal* of March 26 (p 703) Dr R C Webster has replied to some of the points raised in my letter on chronic littritis (March 12, p 594), but it is disappointing that he has not commented on the fundamental difference which exists between our respective views on the production of this condition. I submitted that "acute infection of the glands of Littré, in varying degree is commonly associated with acute urethritis, and reference to *Gonorrhoea and Its Complications* (3rd edition Bulliere Tindall and Cox, 1922), in which the pathology of acute urethritis is authoritatively described by Georges Luys will confirm this statement. It is therefore logical to conclude, as I have done that the production of chronic littritis is dependent on failure to promote and maintain adequate drainage of the infected glands and ducts.

Dr Webster has explained his interpretation of the production of chronic littritis in the following statements, extracted from his original paper (*Journal* February 26 p 448) (1) The essential factor in causation appears to be improper treatment—that is treatment in which the urethra is exposed to fluids at high pressure', (2) 'the patient using a hand syringe can readily produce very

high intra-urethral pressure", and (3) 'in many cases from six weeks to three months' use of the hand syringe is sufficient to produce chronic littritis'. Surely the correct interpretation of the latter time limits depends on the fact that chronic littritis can only be diagnosed after the acute urethritis has abated. This theory of high pressure implies that infective material is forced into the ducts and glands of Littré, and although I cannot disprove this statement personally Luys states 'The organisms within them (the glands of Littré) defy all irrigations, injections, and instillations, as the fluids used fail to reach these recesses'. This explanation by Dr Webster of the production of chronic littritis is in opposition to the known pathology, contains no practical proof that the patient using a hand syringe does actually produce very high intra-urethral pressure, and, to my mind at least, is unconvincing.

When cases of acute urethritis are properly and regularly irrigated with suitable solutions by means of a douche—chronic littritis seldom develops, as the regular lavage and distension of the urethra prevents obstruction of the ducts and thus allows satisfactory drainage of the infected glands. Dr Webster admits that "the capacity of the ordinary syringe is relatively small, so that the urethra is washed with small quantities of fluid at a time," and it is this fact which explains the high incidence of chronic littritis in patients who treat themselves with a hand syringe. I am convinced that high intra-urethral pressures are not produced by the patient irrigating himself with a hand syringe and the results of the following experiment on a cadaver may be of interest in this connexion.

The urethra was tied off immediately anterior to the membranous urethra to represent the action of the sphincter in life and the horizontal limb of a T-shaped glass cannula was introduced into the urethral canal so that the perpendicular limb projected through the urethral wall three inches from the meatus. A manometer, which recorded the intra urethral pressure by supporting a column of water was attached. The pressure obtained by irrigating the urethra from a douche containing two pints of water fixed at a height of three feet above the urethra was compared with that obtained with a 10 ccm hand syringe the diameter of the nozzle being the same in both cases. The mean of three estimations was recorded for each instrument and the hand syringe produced a pressure of 16 inches while a pressure of 27 inches was obtained with the douche can. On all occasions the junction of the nozzle with the meatus was perfect and in the case of the hand syringe the piston was forced down as strongly and as rapidly as possible.

It appears justifiable to compare the figures obtained although no value is claimed for them is absolute estimations, and it is safe to say that the pressure obtained with the hand syringe in these experiments was higher than that which could be achieved by the patient himself, due to the difficulty which he must experience in manipulating the piston and concurrently maintaining an efficient junction between the nozzle and the meatus.

Dr Webster misquotes me when he credits me with the statement, "Failure to promote and maintain adequate dilatation of the urethra," and I seriously question the accuracy of his reproving remark that "the normal function of the urethra is to pass fluids at low pressures hence the use of high pressures in treatment is unphysiological." If this statement is true it must be "unphysiological" on our part to tell patients suffering from gonorrhoea to drink as much water as possible, for the normal stream of urine on micturition even through a littré-meatus, in patients in whom the water intake is considerable is not suggestive of a low intra urethral pressure—I am, etc,

Liverpool, March 31

SYDNEY M LAIRD

## Weil's Disease

SIR—Dr R Nuttall (*Journal* March 19 p 621) in describing a fatal case of Weil's disease mentions the widely different figures for fatality rates and suggests that these differences might be accounted for by difficulties in diagnosing atypical cases: this is undoubtedly true. How far the prognosis can be influenced by the use of anti leptospiral serum is another important speculation. The paucity of records bearing on this question suggests that serum is not largely used. It would appear however that when used prophylactically or in the early stages of an infection experimentally or clinically the serum now available is of the greatest benefit against the strains of leptospira met with in this country although in the later stages of the disease the evidence of its value is perhaps not so clear. Nevertheless now that anti leptospiral serum can readily be obtained it seems worth while in view of the difficulty of forecasting the course of any case of Weil's disease urging that specific serum be used as early as possible in every case of this infection—I am etc

London W1 March 28

F MURGATROYD

## Foreign Colleagues in Distress

SIR—In your issue of March 26 (p 705) eighteen British medical men comment on the situation in Austria and urge colleagues in all countries to watch the progress of events with the closest attention and to do all in their power whether by public protest or by public or private assistance to stand by any members of our profession who may suffer hardship under the new regime.

It is not I fear too cynical to hold that the two words I have italicized in this quotation are the only ones of value. More eminent men than even our eighteen colleagues have produced not less eloquent protests during the last five years. The feelings of the eminent authors have been relieved perhaps our feelings have been vicariously relieved that is all. The relief of misery requires personal sacrifice. Perhaps the time will soon come when a conflict of professional self interest and Christian charity may be rather grim but there is an intermediate stage. The Society for the Protection of Science and Learning (formerly Academic Assistance Council) has worked for the salvation of oppressed scholars and scientists during the last five years. Medical scientists have formed a considerable proportion of our clients and as we do not concern ourselves with practitioners but with displaced academic workers questions of mere professional competition do not arise. No patriot can truthfully accuse us of taking bread out of an English mouth to fill the belly of a foreigner. What we have done has been to help persons well fitted to advance medical knowledge to continue to do so. Most of our subscribers have been themselves academic workers or teachers in schools, few of whom have news value and fewer still pay supertax. They have not written to the Press but they have sacrificed money and convenience. It is much easier to write letters than to fit a stranger guest into one's department to beg here and there to try to interest an influential but indifferent A or a very busy B in some piece of work, intrinsically good enough but not made the best of by a shabby, anxiously ridden foreigner speaking broken English.

Although I am writing a begging letter (of a strictly unofficial kind) I shall not follow the time honoured practice of describing harrowing cases. In the first place they might be identified and if so the emotional cruelty of a child wielding the strength of a giant might be employed

to torture in some petty way the relations of known persons. In the next place I dislike being more emotional than I can help in public. To avoid that danger I will be flippant with G K C.

I know you vetoed at Earl's Court  
That brutalizing Billiard Show  
Quite so yes yes this o-called sport  
Yes so-called Christian strikes a blow  
Yes o-called Twentieth yes I know  
Degraded postures a player kicks  
The billiard marker with his toe  
—But will you lend me two and six?

Few of us who can read and none of us who have been working for the cause these five years need to be urged to watch the progress of events with the closest attention. What we need is to be given (no lent) two and six. Even postage stamps (saved from letters or post addressed to you and other editors) would be thankfully received by the Society for the Protection of Science and Learning 6 Gordon Square WC1—I am etc

April 2

MAJOR GREEN 1907

## Corporal Punishment

SIR—A letter from Mr Victor Bonney appeared in the *Journal* of April 2. Was it to invite comment? The letter begins on one page and ends on the next and as you turn the page you pass from thought which is proper to 1938 to that which characterized the ethics of perhaps the Stone Age. A brutal criminal has injured an individual and offended against social order. Can we seriously believe that the victim of such a crime would be pleased or helped or suffering by imagining the corporal punishment of his aggressor? Happily men have long ago realized that personal revenge has no place in a civilized community and the community as a whole has taken in trust the interests of those who are wronged. In discharge of this trust we have inflicted corporal punishment up to the present time. If the best informed opinion now tells us that it should be abandoned we ought to be thankful that our more merciful feelings are sanctioned and we should direct our aggressive action towards breaking down the social conditions which produce crime. I am not a lawyer but is there not some confusion in Mr Bonney's letter between the administration of justice in civil and criminal proceedings respectively?—I am etc

London W1 April 4

GRACE NICOLE

The Council of the Royal Society of Arts (John S. C. Adelpy W.C.2) give notice that the next award of the Society Prize for a work on medical jurisprudence will be made on January 1939 the ninety fifth anniversary of the death of Dr Swiney left a sum of money to the Royal Society of Arts for the purpose of presenting a prize on the first anniversary of his death to the author of the best published work on jurisprudence. The prize is a cup of value £100 and money to the same amount. The award is made by a joint committee of the Royal Society of Arts and the Royal College of Physicians which appoints special assessors. The prize is offered alternately to general and general jurisprudence but is at present reserved to the former. It is to be given to the author of the best published work on jurisprudence. Any person desiring to submit a work in competition or of recommendation for the consideration of the judges should do so by letter addressed to the Secretary of the Society not later than November 6.

## Obituary

### T A McCULLAGH, M R C S

By the death of Dr Thomas Alexander McCullagh J P, DL at the age of 85, South Durham has lost an outstanding personality. The son of a distinguished Wesleyan divine—the Rev Thomas McCullagh—he received his medical education at Guy's Hospital. After qualification as M R C S, L R C P and a brief period of work in Liverpool and Swinton he went to Bishop Auckland in 1877 where he joined Dr Jobson as junior partner, subsequently continuing in the same practice until 1923 when he retired from active work, though he continued his appointment of medical officer of health, held for many years until 1937.

His interests were very numerous—riding, hunting, shooting, racing, golf, and walking—but in addition to these pursuits of the country doctor he was a great reader with a wide knowledge of general literature. Tall, of distinguished appearance and gentle manner, his was a great presence in the sick-room, and his reputation extended far beyond the area in which he worked. His practice included attendance on many county families in the more prosperous days of Durham county, and he was thus brought into contact with many distinguished figures in various walks of life—political, social, artistic—of whom he had many reminiscences. He was Deputy Lieutenant for the County of Durham under Lord Londonderry, and also one of the oldest members of the Bishop Auckland magisterial bench. In his early days he joined the old Volunteers as regimental surgeon and continued in that capacity as brigade surgeon lieutenant-colonel until that force was merged in the Territorial Force, in which he held the rank of lieutenant-colonel. He received both the Volunteer and Territorial Long Service Decorations. With his passing yet another of the old school of county doctors has gone, a type that is unhappily disappearing. Courteous, gentle, erudite, and yet with interests which enabled him to meet on their own ground any type of patient in his wide area, it was a privilege to meet him and an honour to know him well.

G H

The Bishop of Durham (Dr Hensley Henson) writes

When I came to live in Bishop Auckland nearly eighteen years ago I made the acquaintance of Dr McCullagh who had just retired from the active exercise of his profession and was living hard by the Castle Gates. We soon became fast friends and frequent companions. He was wont to take his "constitutional" in the Castle Park, and I often joined him. His interests in books, birds and politics largely coincided with my own, and his long and intimate knowledge of the county gave a special interest and value to his conversation. He often borrowed books from me, and, unlike many borrowers, he always returned them. He was an omnivorous yet discriminating reader. More than most men whom I have known he combined the urbane manner and tolerant habit of a man of the world with the genuine piety and religious habit of a true Christian. He was indeed both. His long acquaintance with "all sorts and conditions of men" had made him take an indulgent view of normal humanity but it had deepened his belief in Christianity as the deepest truth for man. His neighbours, very various in social type and condition regarded him with affectionate respect. He was everywhere greeted with

something more than normal heartiness. Bishop Auckland was proud of the stately old man, whose presence added dignity to the rather drab aspect of the town. His absence will be felt and lamented.

### J LOCKHART LIVINGSTON, M D

We regret to announce the death on April 2, after a long illness, of Dr John Lockhart Livingston of Hursley, near Winchester. He was the senior partner in a firm practising at Hursley, Southampton, and Eastleigh, and had long been a prominent worker in the British Medical Association, enjoying the confidence of all his colleagues over a wide area.

After studying medicine in Belfast and Dublin Dr Lockhart Livingston graduated with honours in 1886 as M D, M Ch, and M A O of the Royal University of Ireland, and won a clinical gold medal at the Ulster Hospital for Children and Women. He was then house surgeon for two years at the Bristol Royal Hospital for Sick Children and Women before settling in Hampshire, where he held for many years the appointments of medical officer and public vaccinator for the Hursley Union, medical officer of health under the Hursley Rural District Council, and medical officer to the Post Office. During his earlier years of practice he contributed clinical notes to these columns and elsewhere.

Dr Lockhart Livingston joined the British Medical Association fifty years ago, and served, with one break, as representative of his Division at the Annual Representative Meetings from 1920 to 1935 inclusive. He was president of the Southern Branch in 1920 and chairman of the Winchester Division in 1922-3 and again in 1927-9. He had also been president of the Southern Branch of the Society of Medical Officers of Health.

Dr FREDERICK THRESHER GRIFFIN, who died on March 17 at his residence in Southampton at the age of 75, was the son of the late Dr R W W Griffin of Southampton and grandson of the late Dr Richard Griffin of Norwich and Weymouth, who was a pioneer in the founding of the Poor Law Medical Officers' Association. After leaving Epsom College he received his medical education at the University of Edinburgh, where he graduated M B, C M in 1892, and after his father's death began to practise in Southampton. During the war Dr Griffin was attached to the staff of the military hospital at Highfield. He was for many years medical officer to the Southampton Dispensary and to the Southampton Seamen's Orphanage for Boys. After the war he was actively engaged in work under the Ministry of Pensions, and for a time was chairman of the Medical Board for the Southampton area. A very keen sportsman in his earlier years, he was for long a member of the Hampshire Cricket Club, and had once the distinction of catching Dr W G Grace in the deep field on the County ground. He had also played Rugby for Hampshire and the Trojans. He was an original member of the Old Shirley Golf Club and of Stoneham Golf Club. More recently he took up bowls, becoming a member of the County Bowling Club. He was a member of the Southampton Medical Society. Keenly interested in old china, he amassed a valuable and well-selected collection at his home in Winn Road. He leaves a widow and one son.

Dr SAMUEL MOORE, one of the oldest medical practitioners in Leeds and a former member of Leeds Corporation, died at his home in Headingley on March 20. He was born at Newtownards, Co Down, in 1863, and studied medicine at Belfast, graduating M D of the Royal University of Ireland in 1885 and M Ch with honours in 1886. After a short period as assistant at Denholme, Bradford, he moved to Leeds, and was appointed district

medical officer for Holbeck Union in 1897. Dr Moore was a member of Leeds Corporation from 1910 to 1913 and had been deputy chairman of the Highways Committee. He joined the British Medical Association in 1889 and was chairman of the Leeds Division in 1922. For ten years he was vice president of the Leeds and District Ulster Society. His son Dr John Moore has been in practice with his father for some years.

Dr JAMES WOOD, deputy mayor of Brighouse, Yorks, died on March 26 at the age of 68. He was mayor of the borough in 1915-6. Dr Wood was born in Scotland and received his medical education at the University of Edinburgh, graduating M.B. C.M. in 1895. He had practised at Brighouse for forty-one years and was medical officer to the Smith Orphan Homes. He held office as chairman of the Health Division of the British Medical Association in 1927-8. At the funeral on March 29 medical men and members of the Town Council acted as bearers and representatives of public bodies and many organizations attended the service.

Dr RICHARD REGINALD SLEMAN, who died at his residence in Norwood on March 26, had a most distinguished record during the South African and the last war. He received his medical education at Cambridge and St Mary's Hospital, qualified L.S.A. in 1888 and obtained the Durham M.D. in 1906. In the South African War he was surgeon major (senior medical officer) in the City of London Imperial Volunteers in 1900 and was present at the battles of Zand River, Dornkop, Diamond Hill and Fredericksburg. He received the South African Medal with four clasps and the Freedom of the City of London was conferred upon him. He had been an instructor in the Voluntary Ambulance School of Instruction and received the proficiency certificate of the Army Medical Training School, Aldershot, with special mention in 1897. He served with the rank of lieutenant colonel in command of the 1st City of London Field Ambulance and was A.D.M.S. of the 28th Division B.E.F. He was an Officer of the Order of St John of Jerusalem and had been awarded the Volunteer and Territorial Decorations, the Order of the White Eagle of Serbia (1917) and the Order of the League of Mercy in 1919. He was Deputy Director of Medical Services of the Malta Command in 1914 and 1915. Dr Sleman was a vice-president of the League of the Order of Mercy and an inspector of hospitals for that League. He had been a member of the British Medical Association since 1891.

Dr ARCHIBALD WILLIAM WALLACE DAVIDSON died on April 1 at his home in West Kilbride, whither he retired two years ago. He was born in Glasgow on May 28, 1875, the son of Alexander Davidson and from Avon Academy went to study medicine at the University of Glasgow, graduating M.B. Ch.B. in 1900. For more than thirty years he practised at Salcoats, Avonshire, in succession to his uncle, the late Dr Wallace, and was parochial medical officer for Stevenson. When he left Salcoats in 1936 the townspeople gave him a testimonial.

We regret to record the death in London on March 27 of Dr HENRY REYNOLDS BROWN of Maldon, Essex. Born at Dunoon in 1868, the son of the Rev. George Brown, he was educated at the Lycée de Pau in France and the University of Edinburgh, where he graduated M.A. in 1890 and M.B. C.M. four years later. He proceeded M.D. in 1901. His earlier appointments included those of house surgeon to the Edinburgh Royal Infirmary, junior assistant in the pathological department of Edinburgh University and assistant physician to the Crichton Royal Institute, Dumfries and Mavisbank Asylum. During the war he held the commission of captain in the R.A.M.C. and served in France from 1914 to 1917. He subsequently practised at Maldon, where he was medical officer of health of the urban and port sanitary districts and medical superintendent of the isolation hospital. He was also a J.P. for Essex. Dr Brown had been for

forty-six years a keen supporter of the British Medical Association. He was honorary secretary of the Mid Essex Division in 1922-3 and chairman in the following year. He was a representative at the Annual Meeting of the Association in Portsmouth in 1923, president of the Essex Branch in 1929-30, and a member of the Rural Practitioners Subcommittee from 1931 to 1937 and of the Distribution Committee from 1936 onwards.

The death took place at his residence, Burnvale, West Calder, on March 28, after a short illness of Dr WILLIAM YOUNG, O.B.E., J.P., one of the best known practitioners in the Lothians district. He was born in 1856 at Bathgate and taking a medical course at Edinburgh University graduated M.B. C.M. in 1880. After periods of residence in Glasgow Royal Infirmary and in the Royal Maternity Hospital at Glasgow and postgraduate study at Vienna and Paris, he began practice at Addie Well and later settled in practice at West Calder. There he continued in active work for fifty-two years. In addition to the cares of a large general practice, Dr Young took a great interest in local public affairs. He attained the rank of major in the R.A.M.C. (T.A.) held the Volunteer Decoration and in recognition of his services during the war received the O.B.E. He was also for many years keenly interested in education and was a member of the West Calder school board and later of the Midlothian education authority from 1895. Joining the Midlothian County Council in 1910, he acted for some time as chairman of its public health committee and served on a number of its other committees until his death. He also did much to encourage a local pipe band. On completing his jubilee in practice two years ago, Dr Young was presented by his patients and friends with a cheque for £300 and a silver salver. He is survived by his wife, four daughters and two sons, of whom one is an administrative medical officer under the London County Council.

The death is announced of Dr MAGNAN of the Collège de France. He had for many years specialized in the study of flight and its application to the physiology of aviation.

## The Services

### HONORARY PHYSICIAN TO THE KING

Lieutenant-Colonel L. T. POOL, D.S.O., R.A.M.C. has been appointed Honorary Physician to the King in promotion to the rank of Brevet Colonel, vice Lieutenant-General James A. Hartigan, K.C.B., C.M.G., D.S.O., who has retired.

### ROYAL NAVY MEDICAL CLUB

The twenty-fourth annual dinner of the Royal Navy Medical Club will be held at the Travancore Restaurant (Empire Suite), Piccadilly Circus, W., on Friday, April 22, at 7.0 to 8 p.m. Particulars can be obtained from the honorary secretary (Surgeon-Commander M. B. Macleod, R.N.), Medical Department Admiralty, S.W.1. Medical and dental officers from the Royal Navy or Royal Naval Volunteer Reserve are eligible for membership of the Club.

### DEATHS IN THE SERVICES

Surgeon Rear Admiral DONALD TEMPLETON HASKIN, R.N. (ret.), of Achnitry, Somerset, died at Exeter on March 26. He was educated at University College, London, and took the M.R.C.S. and L.S.A. in 1879, the L.R.C.P. in 1882 and the M.B. Lord. in 1887. He held the post of assistant surgeon at University College Hospital in 1889 and entered the Royal Navy in February 1890, rising to the rank of Surgeon Rear Admiral on August 7, 1917, and retiring in 1917. He was surgeon of HMS Curlew on the Australian Station. He received the thanks of King's College and the Government for services of the wounded at Apia in the Samoan rebellion in 1898. He also served through the war of 1914-18, receiving the medals. At the time he held the post of senior commander of medical services in the British Overseas Command, the Ministry of Pensions.

## Medico-Legal

### THE TITLE "DOCTOR"

The Medical Act, 1858, imposes a fine upon any person not on the *Medical Register* who wilfully and falsely pretends to be, or takes the title of, among others, a physician, doctor of medicine, or surgeon. The question of whether an unqualified medical practitioner who holds a genuine degree, awarded by a reputable university, of doctor in some other subject than medicine may call himself "doctor" has never been fully argued before the courts. In March, 1936, the Brighton magistrates, at the instance of the Medical Defence Union, convicted an unqualified practitioner who called himself "Dr Deacon," but he had no good claim to the title. Recently the Union wrote to Miss Ethel Mellor, who practises osteopathy in Welbeck Street, as follows:

Dear Madam—My attention has been drawn to a card on which appears your name with the description or designation "Dr" preceding your Christian name. In view of the recent decision which was secured at Brighton in the Deacon case I should be glad if you will advise me that you will in future refrain from using this designation, which has been held to be an infringement of section 40 of the Medical Act, and which can be confusing and misleading to the public. Many other unregistered practitioners who are practising as osteopaths have already indicated their willingness to come into line with the recent decision and have amended their plates and notepaper accordingly.

Miss Mellor sued the Union for libel, pleading that it meant by that letter, and by others which followed, that she had no right to her title of "Dr" and was unlawfully, wilfully, and falsely using it, implying that she was a doctor of medicine or a registered medical practitioner, that she was dishonourable, had no learning, qualifications, experience, or credentials, was actuated by base motives, and used the title of "Dr" for fraudulent purposes. She conducted her own case and proved that she was a doctor of science of the Sorbonne University in Paris and a doctor of osteopathy of an American college. Her doorplate bore only her name and the prefix "Miss," but she used a descriptive card which bore the name "Dr Ethel Mellor, A.R.C.S., D.Sc., D.O., Osteopathic Practitioner," and her address. She did not allege that the letters of which she complained had been "published"—that is, brought to the notice of any third party other than the office staff of the Union—but complained that they were on the file for others to see. Mr R. P. Croom-Johnson, K.C., for the Union, submitted to the Lord Chief Justice, who tried the case on March 28 and 29, that there was no case for him to answer, and Lord Hewart agreed. He said that the words complained of were not reasonably capable of a defamatory meaning, but even if they had been, on Miss Mellor's own admission they were published on a privileged occasion, and there was no evidence of any malice on the part of the Union. The action therefore failed, and it is difficult to see why it was ever brought. The question of whether the plaintiff's use of the title "Dr" is within the Medical Act or not remains open, but on the face of it there seems to be nothing about her descriptive card which could mislead anyone into thinking she is on the *Medical Register*.

### A TESTATOR'S MENTAL STATE

A testator may suffer from serious mental disability and yet make a valid will. The working of the law in such cases was well illustrated recently when Mr Justice Langton pronounced in favour of a will made by a testator whom he found to have suffered from a marked delusion on a certain subject striking out only a part

of one codicil which he held to be tainted with that delusion.<sup>1</sup> In a still more recent case heard by Mr Justice Henn Collins, the brothers of a testator put forward a will for probate and his son sought to show that it was invalid on the ground that, owing to arteriosclerosis and cerebral haemorrhage, the deceased was not of sound mind, memory, and understanding, and did not know and approve the contents of the will.<sup>2</sup>

The family doctor said that four days after the will was executed he found the testator in a very confused mental state, with a childish manner, and diagnosed cerebral thromboses. Almost every time he saw the testator his conversation was abnormal; he thought he was in the thick of the Abyssinian war and that he was back in his soldiering days. He was very suggestible. Dr J. G. Porter Phillips, stating his opinion on the evidence he had heard, said that persons suffering from cerebral thrombosis were able to pull themselves together and focus their attention on the subject matter before them. He thought the testator's mind was, until two days after the will was made, disordered by arteriosclerosis and not by thrombosis. Dr R. D. Gillespie, also giving evidence of opinion, said that the symptoms during the three months preceding the will showed a progression of the disease, and that he did not think he would himself have witnessed the will, but he would have been swayed by the circumstances of the testator's instructions and manner at the time. The testator might have formed a warped judgment and yet have understood what he was carrying out. The brothers, on the other hand, brought evidence to show that the testator had displayed considerable acumen in the matter of the will, had focused his attention on its terms for a full hour and had dealt lucidly with the questions which the solicitor had raised. He had said that he was making no provision for his son because his son was already provided for. There had been an unfortunate quarrel between father and son, and the father had formed the view that the son had taken a grasping attitude towards some of his property.

The learned judge pointed out that the question to be determined was one of fact and degree, and came to the conclusion that the testator knew and approved of the contents of the will. He was satisfied that the testator's view that the son was amply provided for was not an insane one. The real cause of the son's disinheritance was the quarrel; the son had taken a line which would have antagonized any father in the testator's position. There had been justification in the testator's mind other than a reason produced by disease, and he was satisfied that the testator was of sound disposing mind when he executed the will.

### A LEGACY TO PROVIDE AMUSEMENT

In leaving money to charity it is as well to make sure that the institution chosen for the gift not only exists but is also capable of using the gift in the intended way. In a case reported in these columns some time ago<sup>3</sup> the testator made a substantial gift in his will to a non-existent institution. Recently a gentleman left £1,000 each to the Royal Hospital and Home for Incurables and the National Benevolent Institution, and directed the governors to use the income to provide some form of amusement to be settled by a committee of five patients.<sup>4</sup> The Royal Hospital, answering a summons in the Chancery Division to determine the validity of the gifts and that they were prepared to accept the legacy and carry out the testator's intentions. The treasurer of the National Benevolent Institution, however, declared that it did not possess any hospital or almshouse but provided small pensions for persons who lived in their own homes and could not be described as patients. Mr Justice Simonds said that the question was one of construction. He felt justified in saying that the gift

<sup>1</sup> *Re Bohrmann*, *British Medical Journal* 1938 1 43 (February 19).

<sup>2</sup> *The Times* March 16 and 17. *North v North*.

<sup>3</sup> *British Medical Journal* 1935, 1 809.

<sup>4</sup> *Re Hovenden decd*. *The Times* March 16.

was made to a charitable institution and indicated a general charitable intent on to which is added a particular intention which could not be carried into effect by the National Institution. The gift prevailed though the condition could not be fulfilled. No question arose out of the gift to the Royal Hospital.

The court will always apply what is called the doctrine of *cy pres* in a case where there is a general intention to benefit charity although there may be a difficulty about the particular application of the terms in which the gift is made. It will carry the testator's intention into effect as nearly as possible. No one can doubt that in this case the learned judge took the wise and obvious course.

## Medical Notes in Parliament

In the House of Lords on March 30 the Royal Assent was given to the Blind Persons Act, the Population (Statistics) Act, the National Health Insurance (Amendment) Act, the Housing (Financial Provisions) Act and to other Acts.

The Housing (Agricultural Population) (Scotland) Bill was read a first time in the House of Lords on March 30. In the same House on March 31 the Street Playgrounds Bill was read a second time and the Dogs Amendment Bill a third time. Six Lords were appointed to a joint committee of both Houses on the Collecting Charities (Regulation) Bill.

On April 3 on the motion of Viscount Gage Lord Addington and other Peers were appointed to join with a committee of the House of Commons to consider the Food and Drugs Bill.

The Army and Air Force (Annual) Bill was brought from the Commons on April 5 and read a first time. The Rating and Valuation (Postponement of Valuations) Bill passed through committee. The Administration of Justice (Miscellaneous Provisions) Bill was read the third time and passed.

The House of Commons this week again discussed foreign affairs and also read the Coal Bill a third time.

The Nursing Homes Registration (Scotland) Bill to provide for the registration and inspection of nursing homes in Scotland and for purposes connected therewith was presented in the House of Commons on March 31 by Sir Douglas Thomson supported by Major Neven Spence, and was read a first time.

### The Medical Services in Army Expansion

The Parliamentary Medical Committee meeting at the House of Commons on April 3 with Sir Francis Fremantle in the chair discussed the British Medical Association advertisements in favour of pasteurized milk. The Committee also considered the Infanticide Bill, the Food and Drugs Bill and the Contraceptives Bill. Draft Aircraft Regulations to prevent the communication of infectious diseases by air came before the Committee.

General W. P. MacArthur, Director General of the Army Medical Service, then spoke on that Service and on the medical side of Army expansion. He said the application of the scheme recommended by the Warren Fisher Committee for short term medical commissions in the Army was working most satisfactorily. Of the first contingent of temporary officers all had applied for permanent commissions and twelve out of fifteen had received them. The medical services of the Territorial Army were being brought back to full strength with three field ambulances to a division. This proportion had previously been reduced to one. Provision was being arranged for other medical dental and nursing services to the Territorial Army. In addition twenty nine Terri-

torial General Hospitals were being organized and the necessary provision of material and personnel was well advanced. Difficulty was encountered in fitting in the Territorial provision with the medical side of schemes of air raid precautions under the Home Office. Other problems of co-ordination were satisfactorily adjusted by a co-ordinating medical committee under the Committee of Imperial Defence.

The Parliamentary Medical Committee then discussed with General MacArthur questions of nutrition of food and of recruiting standards. They learnt that one proposal—never put into effect—from the Army Medical Reorganization Committee of 1902 was that the Director General of the Army Medical Service should have a seat on the Army Council. This appeared no longer to be a special need because the Director General of Medical Services was constantly present at informal consultations with the heads of the War Office and had the direct right of approach to the Secretary of State for War. The Committee was also told of new arrangements for provision of water lorries and water purifying plant for troops.

### Alleged Wrongful Detention under Mental Deficiency Act

On March 28 Mr. LOGAN asked the Minister of Health if his attention had been called to the case of a married man aged 31 Territorial who was arrested at the Ministry of Labour Office, Bootle, by two plainclothes officers who informed him they had orders to detain him until an order arrived from the asylum in which he had been detained fourteen years ago on the grounds that he had not been subject and amenable to proper supervision during the five years he had been at liberty and that on the first day was taking to have the case reviewed. Mr. BERNARD replied that the Minister of Health had caused inquiry to be made in this case. There was a reference to an institution for mental defectives on July 11, 1921, on the authority of an order made under the Mental Deficiency Act, 1913. He was allowed to leave the institution on licence on December 22, 1926. The periods were extended from time to time until May 11, 1934, when the licence was revoked on the ground that its conditions had been broken. The patient was then treated as an escape from licence and was eventually brought back to the institution on February 3, 1935. He was again allowed to leave the institution on licence on March 3. The Board of Control had reviewed the whole of the circumstances of the case and as a result directed the transfer of the patient from the order under the Mental Deficiency Act to a special hospital in respect of him.

Mr. LOGAN: Is it not a fact that the patient has been at all along and that he was released in a week only because the question being raised in the House the examination had not taken place only during the week? Is it not a fact further that this man has been at liberty on an institution for twelve years that he is considered to be perfectly sound and that the Territorial officers under whom he has been working say that he is perfectly sane? Will the Minister say what inquiry he intends to make if a man is considered to be insane and sent to an asylum and treated as a lunatic and what compensation he intends to pay?

Mr. BERNARD: Special reports were made in August last about the case and the special is a man who was not a proper person to be detained in an institution. It was within the discretion of the Board of Control to recommend or not and in fact they did not do so.

Mr. LOGAN said that in view of the outrage on public opinion he would raise the question of the removal of the patient from the House.

### Workmen's Compensation Act Inquiry

On March 29 Mr. TINKER asked the Home Secretary if he was aware that the present proposed amendments under the Workmen's Compensation Act did not take into consideration the injured workmen and that a suggestion was suggested in the report of the Departmental Committee set up to inquire into the Workmen's Compensation Act and

when he intended to announce the conclusions of the Government on the report

Sir SAMUEL HOARE replied that the committee's recommendations involved important changes in the present system which could not be carried out without legislation and he could not foresee sufficient time this session for legislation of this character. It would be an advantage to allow more time not only for the Government but also for industry and for members of Parliament to consider the recommendations of the committee before legislation was formulated.

#### Bill to Regulate Sale of Contraceptives

Mr R. J. RUSSELL in the House of Commons on March 30 introduced a Contraceptives (Regulation) Bill to regulate the public display in shops of contraceptives and matter descriptive thereof to prohibit street trading in such articles and to restrict the public advertisement thereof. He said he had found that of 280 chemists' shops only seven did not stock and distribute contraceptives. In addition a large number of shops dealt with contraceptives only. In one district he found thirty-six of these stores apart from the chemists' shops. In addition there was growing up through the country the custom of buying these things through slot machines outside chemists' shops, outside factories, and elsewhere. Inside factories and workshops touts furthered the sale of these articles. Country districts were infiltrated, and in almost every village someone acted as a tout for the display and sale of these articles. The Bill made it an offence to notify or sell these things to unmarried persons under 18 years but there was nothing in it to stop the sale by chemists or from other stores conducted in a proper manner of contraceptives to those who needed them.

Mr THURTELL opposed the Bill and a division was called but not pressed. The Bill was then read a first time. Its backers included Sir Francis Fremantle, Sir Joseph Leech, Sir Henry Morris Jones, Major Neven-Spence, Dr SALTER, and Dr HOWITT.

#### Health on the Training Ship "Caledonia"

Mr DUFF COOPER stated on March 30 that the number of cases of scarlet fever and rheumatic fever among boys in the *Caledonia* [which is moored at Rosyth] since May 10, 1937, when the first entries were made, were seventy-four and thirty-one respectively. The number of cases of middle ear disease to December 31, 1937, was twenty, since then there had been thirty cases of ear trouble but how many were of middle ear disease was not known. Seven boys suffering from rheumatism with heart complications had been sent to civil hospitals on shore. These numbers were not greater than were to be expected periodically in institutions of the type and size of the *Caledonia*. The amount of sickness there was declining. The position was carefully watched and all the usual precautions to limit the spread of infectious disease were in force. Conditions on the *Caledonia* were modern.

#### Medical Officers in the Navy: Marriage Allowances

In reply to Sir John Anderson who asked about the extension to officers of the medical branch of the Royal Navy of the privilege of marriage allowances, Mr SHAKESPEARE said on March 31 that it had now been decided that there was no reason for making any difference in the case of these officers. It had just been announced to the Fleet that they would receive marriage allowances under the same conditions as other naval officers.

#### Psychotherapy for Convicted Persons

Sir RALPH GLYN on March 25 drew attention to a case on March 15 at Lewes Assizes when sentences of imprisonment were passed on two persons in spite of medical testimony on the need for these persons to have psychological treatment. Sir Ralph asked whether the Home Secretary would consider, after consultation with alienists, an institution where cases could be dealt with which were aggravated by prison

treatment. Sir SAMUEL HOARE replied that psychological treatment of prisoners had been the subject of a special investigation by his medical advisers during the last few years. They hoped shortly to present a report. When this report had been received he would be in a better position to consider the general problem.

#### Foot-and-Mouth Disease

On April 4 Mr W. S. MORRISON replying to Brigadier General Clifton Brown said that the recent outbreaks of foot-and-mouth disease began in October 1937. The disease was successfully eradicated by the middle of January in the group of outbreaks affecting Wiltshire and adjoining counties. Fresh centres of disease appeared in Wiltshire (Calne district) on March 26, in Glamorgan (at Pengam) on March 27, and during the week end at Birmingham and Nottingham and in Northamptonshire. There was reason to suppose that infection might have been present in and distributed from Banbury market on March 24 and if this was confirmed a serious situation would have arisen in view of the extensive distribution of stock from that market.

*Notification of Measles*—Sir KINGSLEY WOOD replying to a question on March 22, said that his attention had been drawn to the fact that during the ten years from 1927 to 1936 there was an annual average of 527 deaths from measles in London alone. The question of making all cases of measles compulsorily notifiable had recently been under consideration by the London County Council and he had informed them that he would be prepared to entertain an application for the making of regulations in regard to the notification of measles in London.

*Nursing Profession: Conditions of Employment*—Sir KINGSLEY WOOD told Mr. Bull on March 24 that the information at his disposal did not enable him to state the pay, the arrangements for the provision of uniforms and board, the usual bathroom accommodation, the number of paid holidays, and the days off and week ends enjoyed by each class. These were among the matters under investigation by the Interdepartmental Committee sitting under the chairmanship of the Earl of Athlone and would be fully dealt with in that committee's report.

*Supply and Disposal of Skimmed Milk*—Lady ASFOR asked on March 24, whether Mr W. S. MORRISON knew that the Food Council in a recent report condemned the waste of six and a half million gallons of skimmed milk. In view of the stress laid upon its value as a nutritive food by the Advisory Committee on Nutrition she asked what action was contemplated to avoid this waste in future. Mr MORRISON replied that he knew of the statement by the Food Council but thought the estimate of gallons should be accepted with reserve. The supply of skimmed milk was inconstant since it depended upon the varying quantities of whole milk available for manufacture into butter and cream and it was in greatest supply when the overflow of whole milk from the liquid market was largest. Moreover, many manufacturers had no facilities for converting skimmed milk into a product which could be conveniently stored, handled and transported. The problem was largely one of finding a steady sale for a highly fluctuating quantity and no satisfactory solution had been found. If skimmed milk were sold for liquid consumption the price would be almost as much as for whole milk. The Ministry of Agriculture desired that people should drink whole milk, not skimmed milk.

*Attested Herds Scheme and Beef Cattle*—Mr PRICE inquired, on March 24, if any assistance would be given to owners of beef cattle in connexion with the scheme for eradicating tuberculosis from the herds. Mr MORRISON answered that under powers conferred by the Agriculture Act 1937, it was proposed to extend the present Attested Herds Schemes as soon as practicable to enable payments to be made in respect of herds maintained primarily for beef production.

M. I. Borz.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 26 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for (a) The 125 great towns (122 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)

\* 76 cases in Belfast alone

† After October 1 1937 puerperal fever was made notifiable only in the Administrative County of London.

Death from puerperal sepsis  
‡ Includes primary form in figures for England and Wales (Administrative County) and Northern Ireland

## EPIDEMIOLOGICAL NOTES

## Diphtheria

Notifications of diphtheria in England and Wales show a decided drop since last week—1,404 cases against 1,446—while the deaths in the 125 Great Towns fell from 41 to 27. London did not share to any extent in this decrease, and the deaths rose from 5 to 8, similarly in Scotland while the notifications fell from 261 to 235 deaths rose from 8 to 12. In Ireland about the same levels of the previous week were recorded. Scarlet fever appears to be decreasing in England and Wales the notifications having fallen from 2,307 to 2,167 while in London they rose from 189 to 200. Despite these decreases, both diphtheria and scarlet fever are much more prevalent in England and Wales than during the corresponding week in the previous nine years.

## Pneumonia

Notifications of pneumonia (primary and influenzal) in England and Wales have fallen since last week—1,409 to 1,254—but in London there was an increase of 12 in the week over 110 reported in the previous week. The figures are below the median value for the last nine years in both England and Wales and London. Deaths from influenza in the Great Towns and in London and Scotland show slight increases.

## Measles

In the 125 Great Towns there were 67 deaths from measles compared with 66 in the previous week, of these 23 (18) occurred in London, 3 (3) in Liverpool, 3 (6) in Manchester, 3 (6) in Plymouth, 2 (2) in Sheffield. The figures in parentheses denote the deaths during the previous week. The London epidemic continues, although possibly the peak has just been passed. 2,477 cases were reported from the LCC elementary schools compared with 2,456 last week and 2,521 in the previous week and the average daily admissions to the LCC fever hospitals were 103 against 94 last week and 101 in the previous week. The number of cases of measles under treatment in the LCC fever hospitals on March 25 was 2,284 compared with 2,079 on March 18 and 1,892 on March 11. On March 25 there were in these hospitals 1,182 (1,211) cases of diphtheria, 844 (830) cases of scarlet fever, 312 (271) cases of whooping cough. The figures in parentheses refer to the figures in the previous week. Notifications in the eleven metropolitan boroughs in which measles is notified were for the week ended March 26 1,315 (1,317) distributed in the different boroughs thus: Battersea 136 (142), Bermondsey 94 (60), Finsbury 28 (30), Fulham 53 (81), Greenwich 112 (111), Hampstead 105 (68), Lambeth 322 (377), St Pancras 171 (143), Shore-ditch 38 (31), Southwark 202 (204), Stepney 54 (70). The figures in parentheses denote the numbers for the previous week. In Scotland 1,495 cases were notified compared with 1,547 in the previous week, the figures for Glasgow were 893 (1,037), Aberdeen 210 (107), Dundee 132 (115), Edinburgh 78 (90), Paisley 51 (55). The figures in parentheses refer to the numbers in the previous week. During the week there were in Scotland 36 deaths from measles compared with 24 in the previous week, of these 27 occurred in Glasgow and 1 in Edinburgh. In Northern Ireland there were 80 cases of measles, of which there were 76 in Belfast alone compared with 106 and 98 respectively in the previous week, while the deaths were 12 of which 11 occurred in Belfast, compared with 8 (6 of which were in Belfast) in the previous week. During the week there were 2 deaths in Eire, both in Waterford.

## Small-pox

In the week ended March 26 there were 131 cases of small-pox in Hong Kong and 131 deaths, compared with

276 cases and 192 deaths reported in the previous week. In the four week period ended March 26 there were in Hong Kong 766 cases of small-pox compared with 632 and 219 in the two immediately preceding periods. Over the same periods the figures were in Bombay 874 (+91), 940 (+45) and 608 (303) respectively, in Calcutta 840 (+61), 431 (273) and 192 (146) respectively, and in Madras 204 (+57), 243 (81) and 301 (82) respectively. The figures in parentheses refer to deaths in the same period.

## Typhus

In the week ended March 19 there were in Morocco 372 cases compared with 411 in the previous week, of these 78 (70) were at Casablanca, 122 (56) at Marrakesh, 20 (47) at Rabat, 6 (19) at Agadir. In the same week in Tunisia the number rose from 41 to 74 and in Egypt there were 85 cases reported compared with 68 in the previous week.

## Medical News

The House of the British Medical Association including the Library will be closed for the Easter holiday from 5 p.m. on Thursday April 14 until 9 a.m. on Tuesday April 15 (Library 10 a.m.).

The offices of the National Fitness Council have been transferred to 1 Queen Anne's Gate Building, Dartmouth Street, SW 1. The telephone number is Whitehall 9060.

The Health and Cleanliness Council (Tottenham School WC 1) has arranged a luncheon to be held at the Horn Restaurant WC on Wednesday April 15 at 1.15 p.m. Lord Horder will be the guest of honor and Dr G. F. Buchanan, President of the Council, will preside.

The jubilee dinner of the Metropolitan Police Staff Association will be held at 7 p.m. on April 28 at the Holborn Restaurant with the president, D. Percy B. Spurgin, in the chair. Among those who have accepted invitations are Sir Philip Game, Commissioner of Police, Sir William Wilson, Mr. Kenneth Marshall, Stipendiary Magistrate at Westminster, Mr. P. B. Skeels, H.M. Coroner, Mr. La Verne, Vice D. G. C. Anderson, Secretary B.M.A. and the Headquarters Medical Staff at New Scotland Yard. Metropolitan police staff can obtain tickets from the hon. secretary, D. A. R. 17-4, Bowson Road SE 17 or Dr. W. G. Jones, M.C., 11 Statham Hill SW.

The Glasgow University Club London will dine at the Trocadero Restaurant W on Friday, March 27 at 7.15 p.m. with Professor E. P. Crichton in the chair. The Glasgow University men who though not members of the club desire to attend are requested to communicate with the honorary secretaries, 62 Harle House, London NW 1.

The annual meeting of the Industrial Health Education Society will be held at B.M.A. House, Tavistock Square WC on Tuesday, April 12 at 4 p.m. The chair will be taken by Mr. Sidney Walton and the speaker will be Dr. R. H. Arthur Greenwood, M.P. (Minister of Health 1947-48).

In our advertisement columns this week the Board of Control invites applications for an appointment as Controller of the Board's staff. The salary commences at £50 per annum rising to £1,200 per annum.

A meeting of the International Society of Medical Hygiene was well attended at Learning on March 10. Under the chairmanship of Dr. Frank Clayton several interesting papers were read by Dr. Collins and Mr. Woodman (Harrogate), Professor Roemer (Germany), Professor Poleski (Poland), Professor Loebl (Austria), Dr. Reinhardt (Czechoslovakia), Dr. N. J. F. (Egypt), Dr. Vassil (Germany), Dr. Loring (U.S.A.) and Professor Phocas (Greece). The guests were entertained at luncheon in the corporation of Learning on Spa and in the gardens and gardens during the afternoon.

On April 6 Dr Edith Summerskill (Soc) was returned as Member of Parliament for West Fulham in the by-election caused by the death of Sir Cyril Cobb. Dr Summerskill polled 16,583 votes and her opponent Mr C J Busby (Cons), 15,162.

The Swiss Society of Internal Medicine will hold its annual meeting at Basle on May 14 and 15 when discussions will be held on Graves's disease and hyperthyroidism and treatment of syphilis of the central nervous system. Further information may be obtained from the President, Professor G Bickel, Rue Saint-Leger 2, Geneva.

The German Association of Internal Medicine held its fiftieth congress from March 28 to 31 at Wiesbaden under the presidency of Professor Assmann of Königsberg. The subjects dealt with were the testing of cardiac function, disorders of the suprarenal capsules and acute inflammatory conditions of the central nervous system. One day was devoted to papers and discussions on vitamins B<sub>1</sub> and B.

The fifty-first Congress of the French Society of Ophthalmology will be held in Paris from May 16 to 19, when M Hambresin of Brussels will read a paper on shock treatment in ophthalmology. Further information can be obtained from M Rene Onfray, 6, Avenue de la Motte-Picquet, Paris VIIe.

In view of the great attention which is being paid at the present time to the disinfection of houses and furniture from the bed bug the Royal Sanitary Institute will hold a further course of instruction in disinfection work, beginning on Monday May 16, and lasting for two weeks. Particulars can be had from the secretary of the Institute, 90, Buckingham Palace Road, SW 1.

On March 26 Queen Mary laid the foundation stone of the new hospital which the Surrey County Council is building at Carshalton to meet the needs of the St Helier housing estate. The hospital is to contain 862 beds, and will cost £1,000,000.

Dr Edward W Archibald, formerly head of the department of surgery, McGill University of Montreal, recently received the honorary degree of doctor of medicine from the University of Paris at a ceremony at McGill.

The Privy Council has nominated Sir Walter Langdon-Brown M.D., and Professor W J Dilling M.B., of Liverpool University to serve on the Council of the Pharmaceutical Society, in succession to Sir Humphry Rolleston and Professor J A Gunn, who have retired.

The Council of the Harveian Society of London has chosen 'The Value of Periodic Medical Examination in the Detection of Disease in Middle Life' as the subject for the Buckston Browne Prize, which consists of a medal together with the sum of £100. The prize is open to any member of the medical profession registered in the British Isles or Dominions and is limited to candidates under 45 years of age. Essays must be sent in by October 1, 1939, to the treasurer of the Society, Mr Cecil Wakeley, 14, Devonshire Street, Portland Place, W 1.

A gold medal is awarded annually by the Hunterian Society for the best essay written by a registered general practitioner resident within the British Empire on a subject set by the society. Competitors—men or women—must be engaged in general practice. The essay must be unpublished and original and be based on the candidate's own observation but it may contain excerpts from the literature on the subject provided reference is made to the articles from which they are taken. The subject for 1938 is 'The Management of Inoperable Malignant Disease in General Practice', and for 1939 'Treatment of Obesity in General Practice'. Candidates should obtain a copy of the rules governing the competition from the honorary secretary Mr Arthur Porritt, 27, Harley Street W 1 before sending in their essays, which must reach him by December 31. The gold medal for 1937 was awarded to Dr J Wilson Reid of Anglesey for his essay on 'The Prognosis and Care of Heart Disease in General Practice'.

The Save the Children Fund (20, Gordon Square, London WC 1) which is engaged in the promotion of child welfare at home and abroad, announces that its panel of honorary medical advisers has been enlarged and now consists of the following: Sir Francis Fremantle, M.P., M.D. F.R.C.P., Dame Louise McIlroy, M.D., F.C.O.G., Eric Pritchard, M.D. F.R.C.P., and Matthew B Ray, D.S.O., M.D. Mrs Susan Isaacs, D.Sc., the psychologist, has become associated with the Fund as a vice-president, and Dr Ray also fills this office as well as being an honorary medical adviser.

Gifts amounting in all to £6,000 have been received in aid of a scheme for a fracture clinic at the Hull Royal Infirmary. The scheme is the outcome of an address given at Hull by Mr Rowley Bristow on the modern treatment of fractures. To complete the organization a further sum of £4,000 is needed.

In order to meet the need for leaders of physical recreation, the Central Council of Recreative Physical Training has arranged a three months course for women at Anstey College, Birmingham, from April 29 to July 22, a three months course for men at Loughborough College summer training camps for men to be held at the Sir William Dunn Camping Ground, Downe, Kent, from July 30 to August 6 and from August 6 to August 13, and at the Heswall Camp, Cheshire, from August 20 to August 27, and a summer school for women to be held at Milton Mount College, Crawley, Sussex, from July 29 to August 13. Further details can be obtained on application to the Secretary of the Council at Abbey House, Victoria Street, London, SW 1.

At the beginning of this year the *Journal of the National Institute of Industrial Psychology* was issued in a new form as a quarterly under the title of *Occupational Psychology* at the price of 5s. It includes among other things an article by Dr Charles Myers on 'The Mental Hygiene of Intellectual Work,' and one by Dr A H Davis on 'Some Aspects of the Problem of Noise.'

On April 22 the thirty-fifth anniversary of Dr Smith Eli Jelliffe's editorship of the *Journal of Nervous and Mental Diseases* will be celebrated at the New York Academy of Medicine by a neuro-psychiatric symposium in the afternoon and a dinner in the evening. Dr Adolph Meyer will open the symposium, and the other speakers are Drs Earl D Bond, George Draper, Frederick Tilney, Oskar Diethelm, and Karl Menninger. Dr Foster Kennedy will preside at the dinner, and tributes to Dr Jelliffe as psychiatrist and psychoanalyst, as a man, a neurologist, and a bibliophile will be paid by Drs A A Brill, Louis Casemajor, Henry Alsop Riley and Richard H Hutchings.

The February issue of the *Bulletin de l'Office International d'Hygiène Publique* contains articles on typhus in the United States, Morocco, Tunisia, Czechoslovakia, and Soviet Russia, infantile mortality in the Argentine and Yugoslavia, public assistance in Italy, and the demography of the native population in the Belgian Congo. A special supplement is devoted to the demography of the French Colonies.

On April 2, at Kettner's Restaurant, Sir Henry Gauvain, the medical superintendent, was entertained to dinner by the past and present R.M.O.s of the Lord Mayor Treloar Cripples' Hospital, Alton, to commemorate the silver wedding of Sir Henry and Lady Gauvain and the thirtieth anniversary of the hospital. Dr C E M Jones, who has been a R.M.O. for nineteen years, was in the chair.

A National Institute of Nutrition has recently been founded at Buenos Aires under the Ministry of Foreign Relations.

On April 1 a law came into force in Germany by which parrots and similar birds kept for profit or pleasure are to be registered and wear a ring on their claws with the name of the owner. Those that are sick or suspect must be killed. Offenders will be punished with imprisonment not exceeding three years and fines not exceeding RM 10,000.

The Paris Académie des Sciences has nominated Dr Lericq, professor of surgery in the Strasbourg faculty of medicine to fill the chair of medicine at the Collège de France rendered vacant by the death of Charles Nicolle.

## Letters, Notes, and Answers

All communication in regard to editorial business should be addressed to THE EDITOR BRITISH MEDICAL JOURNAL B.M.A. HOUSE TAVISTOCK SQUARE W.C.1

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary B.M.A. House Tavistock Square W.C.1 on receipt of proof. Authors overseas should indicate on MSS. if reprints are required as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary B.M.A. House Tavistock Square W.C.1

THE TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111

THE TELEGRAPHIC ADDRESSES ARE  
EDITOR OF THE BRITISH MEDICAL JOURNAL *Anaesthesia*  
Westcott London

SECRETARY *Medicines* Westcott London  
The address of the B.M.A. Scottish Office is 7 Drumfugh Gardens, Edinburgh (telegrams *Assoc. Edinburg* telephone 24-61 Edinburgh) and of the Office of the In-House Free State Medical Union (I.M.A. and B.M.A.) 18 Kildare Street Dublin (telegrams *Bucillus Dublin* telephone 62550 Dublin)

## QUERIES AND ANSWERS

### Purity of Water

T. G. P. writes: The water supplied by a company is obtained from deep wells sunk in the chalk and is softened by Clarke's process. Occasionally it is of a milky appearance with a deposit on standing. This occurs more particularly when repairs are made to the mains or when a large quantity is drawn off by the fire hydrants. Is this deposit likely to be injurious to the health of consumers? Some of them appear to think that it may be.

### "Lower Critical Temperature"

Dr G. A. FERRABY (Worthing) writes: I am told there is a lower critical temperature below which the automatic temperature regulating centres cease to be effective as it does above 105° F. or a little over. I have been unable to find out what this lower critical temperature is. Can anyone give me the correct figure or a reference to the literature?

### Painful Heel

SIR MORTON SMART writes in reply to D.C.'s inquiry (March 26 p. 712): The fact that the x-ray examination shows points of calcification suggests that the condition is similar to that which arises from a true os calcis spur, the pain of which is usually brought about by bruising of the tissues of the heel on the spur. Many cases of os calcis spur exist but cause no pain until the underlying tissues are damaged by a blow or by jumping on the heel. Even the most painful heels from this cause can be cured by wearing a special support which I designed and which is made to fit the particular case by Mr P. Frantz, 55 Catherine Place Westminster SW.1. It must be realized that the support may have to be worn for some weeks before complete relief of pain results as the object of the support is to prevent pressure on the tissues of the heel and thereby allow the traumatized tissues to recover.

### Income Tax

#### Semi domestic Expenses

YARRUM'S household consists of himself his wife and his working whole time in the practice and a cook and housemaid. Hitherto he has claimed as a professional expense only one-half of one maid's wages. His accountant suggests that he should claim the whole of her wages plus 20% a week for board for the reason that the wife is in practice and therefore the extra maid is employed because of this and is an expense of the practice.

\*\* Assuming that there are consulting and waiting rooms on the premises and that the maid attends to callers and

the telephone we agree that our correspondent is entitled to deduct most, if not all of the wages and board of one maid but it is inadvisable to put forward the remaining suggested above. There is a judicial decision that the cost of a domestic servant necessary to relieve a wife for teaching work was not a deductible expense—it was not incurred in carrying out the teaching duties. That case was argued under Schedule E but the principle seems to apply to Schedule D also and would no doubt be relied on to refuse Yarrum's claim if made on such grounds.

## LETTERS, NOTES, ETC

### Herniation of an Inflamed Appendix

Dr N. CARWARDINE COOPER (Somerset) writes: The following case of appendicitis occurring in a female child is of interest on account of the patient's age. A 10-year-old girl was admitted to the Weston General Hospital with a diagnosis of strangulated right inguinal hernia. The hernial swelling was definitely irreducible but not tense. The child was crying loudly and it was therefore difficult to tell whether the swelling was tender or not. The temperature was normal but the pulse rate was 160. An operation was performed through the usual femoral incision and on opening the sac a certain amount of clear fluid escaped. The lower part of the caecum and appendix were in the sac and were oedematous. The appendix had been swollen and tense and was removed; the gut was returned to the abdomen and the hernial sac ligated. The child made an uneventful recovery. On opening the appendix the mucous membrane was plum-coloured and definitely in an acute stage of inflammation.

### Swallowed Safety-pin

Dr L. ELWELL-JOHNSTON (Wimbledon) writes: Received 1 day a 3-months old infant that had swallowed a safety pin twenty-four hours previously. On inspecting the throat the safety end of the pin could be seen below the uvula at the tip of the left tonsil. An attempt to remove it with sinus forceps failed. The infant cried loudly and the pin descended to a lower level and as careful with the substituting fingers for forceps the pin was held firmly against the lateral aspect of the throat, they grasped with forceps. As the pin was seen it was in the act of being forced forward through the mouth, so it was pushed up behind the soft palate and the other end pulled out. Thus the delivered the safety pin rusted and one end a quarter of an inch long no injury was apparent. While the pin was in the throat the baby had had one difficulty in swallowing and was tussling during the night. The mother had been holding the baby on her lap the day before she had swallowed this pin in her blouse. At intervals when she was asked if she could not find it. Doubtless the pin had dropped into the infant's open mouth.

### Sodium Salicylate Tolerance

Dr C. TRIST GASKING (Harrogate) writes: Sodium salicylate probably still occupies the first place among drugs in the treatment of rheumatism. The following case is of some light on the question of dosage and the duration of treatment. In 1924 I was consulted by a patient in a poor condition and found him extremely deaf. He had been early sixties and into me he said that ten years earlier he was working at Woolwich Arsenal he had been severely attacked of muscular rheumatism. A friend had told him that sodium salicylate was a cure for rheumatism and he had taken upon that advice and finding relief he had continued to take it until he was 50. But even then the rheumatism returned and the preparation was used for ten years. After that time he was almost stone deaf and completely unable to hear. He remained well and quite free of rheumatism for many years.

### Nelson's Seal Cases

A. F. H. writes: In the *M. A. J. W.* this section Nelson in his paper on the history of the seal case in 1850 (March 26 p. 64) the only case of the seal case is a graph letter in the *Post* edition of the *Seal Case* from HMS. *M. J. W.* on April 21 1851 to Nelson's Seal Case the British envoy to Copenhagen made a seal case and it was so intended as a seal case and it was so intended as a seal case and it was so intended as a seal case.

### Swedenborg Stamps

To commemorate the 250th anniversary of Swedenborg's birth which was noticed in these columns on January 29 page 239 Sweden has recently issued two dignified and pleasing stamps, a violet 10 ore and a greenish 100 ore. The design is by the artist Torsten Schonberg after a portrait by Per Krafft the Elder. A laurel branch roofs the legend Emanuel Swedenborg, 1688-1938. A variety of the 10 ore stamp is perforated all round and is described as scarce.

### Toxic Foci

Dr SYDNEY PERN (Ballarat Australia) writes: The appearance of a letter entitled Toxic Focus with Ophthalmic and Deimic Reactions by Dr J E Martin in the *Journal* of July 10 1937 (p. 88) has prompted me to make these few remarks. It is an astounding thing that after so many years of knowledge of this subject so many of these foci are overlooked. I would like to mention a few traps that many fall into. First as regards apical infection of teeth x-ray films are not reliable evidence of infection. It has been shown that 98 per cent of all dead teeth with no signs of apical infection on the film show definite infection on culture. In other words all dead teeth can be accepted as infected. This fact ought to be known to all medical men and dentists. The only evidence of gingival infection that can be relied on if in doubt, is to take cultures from pockets however small with a platinum wire. Unerupted wisdom teeth are often overlooked and are always infected. Broken roots, usually infected are found with surprising frequency in edentulous jaws as are granulomas which have broken off from extracted teeth the finding and removal of which often yield astounding results. As regards tonsils, a casual glance at an anaemic-looking tonsil is usually enough to pronounce it uninfected when it often contains virulent organisms. Frequently no attempt is made to retract the anterior pillars and if no tonsil is visible it is passed as not being a source of infection. If there is any tonsil tissue visible cultures should be taken from the centre, preferably with a capillary glass tube and if this is done sufficiently often it will be found that practically all tonsils are infected because if not infected they naturally atrophy. Sinus infection is more often overlooked than any other. I found that in my out-patient clinic 25 per cent of the patients were so infected. It is comparatively easily diagnosed by a chronic dropping of mucus from behind the palate because where there is pus there must be infection. Morning headaches and liability to frequent colds are usually present. X-ray films can be misleading. Bad headaches often occipital without any discharge may mean locked up pus. Infected gall-bladders are often the cause of many troubles and may present very few symptoms. Pyelitis is commonly overlooked as is prostatic infection. Cervical infection in women does not get nearly the attention it should. These are the usual sources of infection, and if carefully examined will nearly always yield results. It is very unwise to be content with finding only one focus of infection as they are frequently multiple and unless all are removed improvement cannot be obtained.

### Insulin as a Suicidal Agent

However secure their position in relieving the burden of suffering humanity few medicinal agents are exempt from being misused by criminals or by writers of fiction when murder or suicide demands efficient weapons. This is true of insulin. In Dr W Stanley Sykes's story, *The Missing Moneylender* (1931) a doctor kills his victim with an overdose of insulin after his death injecting enough sugar intravenously to restore the blood sugar to its normal figure and thus to abolish the only possible clue. The first case in the literature of attempted suicide by insulin was reported in 1934 by J T Beardwood jun (*Journal of the American Medical Association* 102 765). The patient was a diabetic, and the dose employed was 390 units. Two other cases are briefly mentioned in this paper one of which was a Philadelphia physician. A fourth case is now described by D Donald and L J Foster in the December number of the *Journal of the Michigan State Medical Society* (36 967). The story however both in its clinical and biochemical aspects is complicated by acute alcoholism. A man aged 26 (non diabetic) had heard from a doctor that it was presumably possible to kill a person with insulin without leaving a trace of the cause of death. While in a state of intoxication he took an overdose of 200 units. Admitted to hospital

in coma he remained unconscious for nearly three days but finally recovered. The persistence of coma for forty-eight hours after the blood sugar had returned to normal was probably due to alcohol. He had made a previous attempt at suicide by slashing his wrist with a razor blade.

### Treatment of Parasitic Conditions

Dr F G CAWSTON (Durban South Africa) writes: Clonorchis infection has fortunately not been recorded from South Africa and would seem to be confined to Sino-Japanese areas where fish is eaten raw but reported success in treating this parasitic disease with a gold preparation suggests that the same drug might be of service in allied conditions such as schistosomiasis. Though this line of treatment was suggested to me some time ago I have not heard that it has been attempted. In 1922 I treated hydatid disease successfully with emetine hydrochloride. Judging from the analogous conditions emetine would seem to hold out the greatest promise of success in the treatment of hydatid disease other than by surgical measures but I can find no reference to its use since I brought the treatment to the notice of medical men in Cyprus and Australia where cases were being encountered. In 1927 Bougenault suggested that antimony in the form of an ointment might be employed for the treatment of bilharziasis occurring in children with inconveniently small veins. The typical rash from the use of antimony ointments is readily controlled and does not occur when the drug is introduced into the rectum. Success has been said to follow the introduction into the bowel of large doses of tartar emetic, but as with other alleged cures the reports do not record the recovery of antimony in the urine or an increasing proportion of dead ova escaping with the excreta. Evidence is still wanting to show that enough of a drug can be absorbed by skin or mucous membranes to cause the death of large blood parasites but an early effect on schistosomes by the oral administration of carbon tetrachloride or antimony applied to the skin and bowel wall, suggests that some new line of treatment may yet be devised which will render a course of intravenous injections of tartar emetic or even intramuscular injections of anthiomaline unnecessary. Due consideration of the elimination of antimony supports the use of intravenous therapy for adult blood parasites. The drug may be very rapidly eliminated and I have noted marked discoloration of the urine within a few minutes of injecting the oxyquinoline derivatives.

### Strychnine Poisoning

'B. L. T.' writes: A girl of 20 was brought to me at 2.30 a.m. one night with the story that she had just swallowed a chocolate she had herself filled with strychnine. Gastric lavage was begun soon after 3 a.m. immediately after the first emptying of the stomach which seemed to contain very little, great difficulty was experienced owing to burning of the tube by the patient. This prevented any further lavage and was thought to be due to the girl's obstinacy until, with dramatic suddenness she became quite rigid in a strychnine convulsion. She was hurried off to hospital where at 3.40 a.m. I gave her 10 ccm of sodium evipan intravenously. At once she relaxed into a quiet narcosis. By 4 a.m. she was again having single convulsions which by 4.15 were again becoming tonic so that at 4.20 another 10 ccm of evipan were given. At 5.25 a third dose of 10 ccm was necessary. A smaller dose would have sufficed, because the injection was followed at once by exceedingly shallow respiration for about five minutes. However when the effect of this last injection of evipan wore off there were only occasional violent twitches. The next day there was a little pyrexia but no muscle stiffness such as might have been expected after such violent contractions. The patient brought me later a little talc powder corresponding to the amount she thought she had taken from a bottle of strychnine nitrate in a laboratory to which she had access. A comparable quantity of strychnine nitrate was found to weigh 35 centigrammes, and this the girl had put in the interior of a chocolate cream and had swallowed on an empty stomach so that, allowing for a considerable margin of error one can presume that she had taken a fatal dose.

British Drug Houses Ltd (Graham Street City Road N1) have issued a booklet summarizing recent advances in knowledge of the vitamins with particular reference to their own products. Any reader who has not received a copy can have one free of charge postage paid on application to the firm.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

### 286 Late Effects of Infantile Rickets

M. LANGE (*Dtsch med Wschr* December 17 1937 p 2022) states that too many cases of undetected rickets occur in spite of two decades of prophylaxis and treatment. Correct diet and enough sunshine are the most important factors in the prevention of the disease. Rachitic changes in the skeletal system require attention during infancy; otherwise permanent changes may produce backache, lowering of the capacity for work on account of scoliosis or flat feet, coxa vara and valgus and an increased tendency to arthritis deformans. In adolescence care must be taken not to overtax the strength of patients affected by late rickets. Static conditions should be improved by suitable boots and exercises. Arthritis deformans can thus be prevented or at least stayed off for a considerable period.

### 287 Daily Vitamins

A. SCHELVERT (*Med Klinik* January 14 1938 p 37) points out that since avitaminoses are most common in spring the diet should be carefully regulated in regard to vitamins from late autumn to the end of the winter. The minimal daily requirements of vitamin B<sub>1</sub> have been worked out at 300 international units. Brown bread (wholemeal) is the best source of this vitamin. 100 grammes of wholemeal bread contain 100 units, 100 grammes of vegetables contain 50 units, 100 grammes of potatoes 40 units. As the vitamin is water soluble the water in which vegetables are cooked should not be thrown away. Vitamin C is present in fresh vegetables and fruit on storage much of it is lost. The daily requirements of vitamin C are 25 to 30 mg. Cabbages and potatoes contain much vitamin C. 1200 grammes of cabbage contain 270 mg. of vitamin C. 100 grammes of potatoes 20 mg. (November) and 10 mg. (May). Vitamin C is water-soluble and easily oxidized. Vitamin A being less easily oxidized and fat soluble is not quite so much affected by cooking. Green vegetables and carrots are its most important source. The daily requirements are 4200 international units. 100 grammes of spinach yield 10000 units and butter, heart, kidney, liver, and animal fats are all good sources of supply.

### 288 Thrombosis and Embolism

E. LOMMEL (*Dtsch med Wschr* February 4 1928 p 151) draws attention to the statistically demonstrable increase in the frequency of thrombosis and embolism in Germany since 1923. He does not regard the increasing popularity of medication by intravenous injection as in any way contributory to this increase but attaches much importance to the growing incidence of heart disease and to the rise in the average age of the population. Another factor which in his opinion plays an important part is the increase in the average weight of the community for during the lean years of the great war and the inflation period the frequency of thrombosis declined only to rise again after 1923 with a more generous national dietary. Post mortem observations made in Jena, Basle and Berlin from 7380 patients, 898 of whom had suffered from pulmonary embolism showed that the average weight of the males suffering from embolism was 20 kilos more than the average weight of the male controls; for women the difference was 12 kilos. At his clinic in Jena Professor Lommel has for some time weighed all his male patients between the ages of 15 and 70 and has found marked overweight in 75 per cent of some 1200 persons weighed. He also found that 15 per cent of his male patients

between the ages of 40 and 59 weighed more than 10 per cent over the normal. As for the influence of the average age of the community on the frequency of thrombosis and embolism he notes that in Germany in the period 1901-10 the average duration of life was 46.52 years, the corresponding figure for the period 1922-4 was 61.26 years. Yet another important factor would seem to be the relaxing effects of modern civilization on the muscular tone of persons who amble gently through life instead of strain at daily giving their muscles tonic exercises which are distinct from the violent exercises of youth.

### 289 Nervous Complications of Undulant Fever

P. P. F. ORIOL (*These Paris* 1927 No 831) has recorded seventy-nine cases in patients aged from 10 to 65 years, that nervous sequelae are relatively frequent in undulant fever, any part of the nervous system can be affected. Examples having been recorded of meningitis, poliomyelitis, radiculoneuritis and encephalitis. The most typical complication however is involvement of the meninges which is almost invariably present. In chronic or subacute cases the disease is nearly always an alteration in the cell content of the cerebrospinal fluid.

## Surgery

### 290 Tube colostomy of the Knee

T. WALHEIM (*Hygiea Stockholm* January 19 1938 p 11) gives an account of 143 cases of tuberculous disease of the knee treated in a hospital in Stockholm in the period 1921 to 1924. Of the 125 cases in which the diagnosis was confirmed by question thirty-nine were male. The disease was bilateral in three cases, right-sided in eleven, left-sided in thirty-one. Every age was represented from under 2 years to 69 years, and as many as fifty-eight patients were under the age of 15. A history of trauma was given in thirteen cases, the interval between it and the first appearance of symptoms ranging from two days to three years. In seven cases the disease began as a polyarthritis. In 10 per cent of his cases Pirquet's reaction was negative. The Mantoux reaction was invariably positive but only after it had been repeated with negative results in tuberculin. Guinea pig reactions showed negative results in 40 per cent of cases and in the case of the guinea pig tests were both negative and positive, tuberculous bacilli were found by exploratory excision. A comparison of the results of conservative and operative treatment in 102 cases showed a recovery rate of 71 per cent in cases treated surgically, whereas it was only 38 and 39 per cent in those treated conservatively.

### 291 Fractures of the Neck of the Femur

KAPPEL (*Dtsch med Wschr* January 19 1938 p 151) of the University Surgical Hospital in Würzburg states that the important advances made during the last decade in the treatment of fractures are most noticeable in the treatment of fractures of the neck of the femur. He stresses the painful evolution of the non-operative treatment of these fractures up to the time when Whitman and Lohrer achieved general acceptance of the method of prolonged immobilization. With this method patients are plastered for two to four months and allowed to walk bearing for about a year. Under this system about 60 per cent of such fractures healed, but even then with good functional results. Recently Lohrer has had similar good results in 74 per cent of his cases and in both Whitman's and Lohrer's results patients have been cured of apoplexy and disease of the heart and

lungs have been less frequent in spite of prolonged immobilization than when patients were hustled about early. But though there has been a vast improvement in the conservative treatment of these fractures, Professor Kappis confesses to having wavered and then finally gone over to operative treatment with pegging as carried out by Sven Johansson. The wavering was as recently as 1932, when a survey of the patients operated on in 1923 and 1924 at the Wurzburg Hospital revealed a disquieting proportion of failures. Since then there has been such a marked improvement in operative technique and material that it can now be claimed of the Sven Johansson operation that bony union will be achieved in 90 per cent of cases, and that 90 per cent of the patients surviving the operation will again enjoy the normal functions of the joint. After referring in appreciative terms to the Pauwels operation, Professor Kappis concludes that even old fractures can be satisfactorily dealt with by the Sven Johansson or Pauwels operations provided the choice is made after a complete survey of the situation by a competent surgeon.

## 292 Trigeminal Neuralgia

F C GRANT (*Ann Surg* January, 1938, p 14) points out that although trigeminal neuralgia does not endanger life it may interfere with eating or drinking sufficiently to cause loss of weight and strength. The question of surgical treatment is discussed and the different methods which may be used are described. The transtemporal approach to the sensory root through the middle fossa was employed in 949 operations upon 925 patients with thirteen deaths, an operative mortality of 1.36 per cent. The death rate has decreased steadily in recent years. Trigeminal neuralgia is a condition which appears late in life, and this accounts for the fact that seven of the deaths were the result of cerebral vascular accidents such as embolism. The type of operation to be undertaken depends on the individual case. If pain is not referred to the first division a subtotal avulsion, preserving part of the fibres to the ophthalmic branch, is indicated, but when the trigger zone exists in the second or third division of the sensory area a subtotal sensory root section will relieve pain. The two most common post-operative complications are keratitis in the ipsilateral eye and facial paralysis. A suggested cause of the paralysis is that the stripping of the dura from the floor of the skull just in front of the ganglion damages the petrosal vein or nerve. A partial facial paralysis occurred in 3.4 per cent of cases, but the majority of these recovered completely. There were thirty-five instances of keratitis and it was seen that this complication was not nearly so common after a subtotal section of the sensory root as after a complete root section, nor was it so severe. Paraesthesias were complained of in 130 cases but of these ninety-eight were of the mild type. There were seven cases of recurrence in 359 cases of complete sensory root ablation and forty-four among 590 patients in whom partial section was done. It is obvious that subtotal section of the sensory root with preservation of the motor root is the procedure of choice.

## 293 Perthes's Disease and Osteochondritis Dissecans

A HAAS (*Zbl Chir* December 18, 1937, p 2873) describes what he believes to be the first recorded case of the transformation of Perthes's disease into osteochondritis dissecans of the hip. It was possible radiographically to trace over three and a half years the cure of Perthes's disease in the right hip with at the same time the appearance of the sequestal scale of an osteochondritis dissecans on the head of the femur at the beginning of the observations when the boy was aged 5, x-ray evidences of the latter condition were also visible in the left hip, possibly relics of antecedent Perthes's disease on that side. Dissecting osteochondritis is much more common in the knee and elbow than the hip, where only fourteen cases, it is said,

have been reported. Haas agrees with those who trace a connexion between osteochondritis dissecans and all the so-called aseptic osteochondritic necroses, as seen in Perthes's disease, Osgood-Schlatter disease of the tibial tuberosity, Kienbock's necrosis of the os lunatum, and calcaneal apophysitis, and with Schneider in attributing them to disturbances of metabolism and vitamin assimilation rather than to mechanical influences.

## Therapeutics

### 294 Complications of Chemotherapy

H SAPHIRSTEIN (*Urol cutan Rev* February, 1938, p 101) states that since the introduction of sulphanilamide a number of untoward effects have been reported, such as sulphaemoglobinaemia, methaemoglobinaemia, haemolytic anaemia, leucopenia, agranulocytosis, cyanosis, acidosis and depression of hepatic function. He reports the first case on record in which administration of the drug gave rise to hepatitis and a toxic erythema followed by desquamation. The patient was a man, aged 29, under treatment for gonococcal urethritis, who in addition to local treatment was given in divided doses 40 grains of sulphanilamide daily, and then 20 grains daily for six days. After he had taken a total of 460 grains he developed a generalized maculo-papular rash, yellow discoloration of the sclerotics and skin, and bile appeared in the urine. Seven days after the administration of the drug had ceased generalized desquamation occurred and lasted twelve days. The clinical picture closely resembled that often seen after injections of salvarsan.

295 G RICHARD (*These Paris* 1937, No 842), who reports twelve illustrative cases in patients aged from 7 to 40, states that sulphamido-chrysoidine, though it has given good results in the treatment of streptococcal meningitis, has also given rise to severe complications.

### 296 Malarial Treatment of Gonorrhoea

K BRUDER (*Dein Wsch*, February 5, 1938, p 133) reports the result of malarial therapy in 122 women suffering from acute subacute, and chronic gonorrhoea. The treatment resulted in a complete cure in 86 per cent of cases. The results were somewhat better in acute and subacute than in chronic gonorrhoea. The author considers the effect of the malarial infection akin to that of a non-specific protein shock. The treatment was generally well tolerated, cardiac stimulants were not needed in a single case. In one instance the treatment seemed to be responsible for the development of a psychosis which lasted four weeks. Of the cured cases 41 per cent became re-infected; these were mainly prostitutes, and the value of malarial treatment in such patients is questionable.

### 297 Treatment of Psoriasis

H W SIEMENS (*Munch med Wsch* January 7, 1938, p 5) has investigated the action of different preparations of chrysarobin in a number of cases of psoriasis. The patients were divided into groups of ten, and each group was treated with one compound at a time. The investigation showed that chrysarobin-vaseline is not superior to chrysarobin paste, but its irritant effect is three times greater. The addition of salicylic acid only slightly improves the curative effect of chrysarobin paste but it intensifies the irritant effect of the chrysarobin. The addition of liquid soap to the chrysarobin paste renders the preparation entirely inefficient and non-irritant; the chrysarobin is probably changed chemically by the alkali in the soap. It seems that the toxic, irritating pyrogallol cannot be replaced by lenigallol in the treatment of psoriasis though in two cases out of thirty lenigallol was more effective than pyrogallol.

## Ophthalmology

### 298 Prevention of Blindness in the Tropics

A F MACCALLAN (*Brit J Ophthalmol* February 1938 p 65) reviews the history of ophthalmology in Egypt and gives the present day causes of blindness in that country. Acute conjunctivitis has a distinctly seasonal variation closely related to temperature, humidity and the breeding time of flies. Trachoma probably originated in Mongolia spreading westward with the Mongol invasions. The vast amount of blindness due to small pox has been abolished by vaccination. Industrial causes of blindness are infrequent in Egypt and India but keratomalacia is common in India. Squint is a frequent cause of blindness. Means of prevention include the proper provision of ophthalmic hospitals with facilities for pathological and bacteriological investigation. Schools must be inspected and treatment provided in them and children's dispensaries and ophthalmic welfare clinics established in the towns. Native-trained hospital attendants are very helpful in remote country districts and improvements in sanitation lead to a marked diminution in eye disease. By adopting these measures in Egypt the percentage incidence of blindness has been reduced from 19.2 in 1911 to 6.2 in 1934.

### 299 Corneal Grafting

V FILATOFF (*J med Ukraine* 1937 7 3 745) has been able to clarify corneal opacities by means of corneal grafts taken from the cadaver and preserved in cold storage. He believes that the transparency of the cornea is due to the disposition in space of its constituent elements which is determined by a substance or a group of substances normally present within the cell. Only those opacities which consist of damaged corneal tissue beneath the graft corneal scars consisting of connective tissue remain uninfluenced. The results obtained from grafts taken from the cadaver are better than those with grafts borrowed from a living person. The author has obtained excellent results from his method in one case of tuberculous keratitis, one case of herpetic keratitis, three cases of trachomatous pannus, six cases of parenchymatous keratitis and one case of sclerosing keratitis.

### 300 Black Cataract

Y SHON (*Arch Ophthalmol* Paris December 1937 p 1057) analyses thirty six black cataracts finding that in most the vision after operation is poor, there being such fundus lesions as myopic choroiditis, pigmentary degeneration of the retina and optic atrophy. The lens is slightly smaller than in the ordinary senile cataract and in some cases brilliant granules have been seen with the microscope. Certain black cataracts forming a class by themselves and distinct from true black cataracts follow intraocular haemorrhage. Of six of the cases examined histologically by the author five had pigmented granules. He believes the colour of the lens to be due to melanin which under certain conditions becomes granular.

### 301 Menopausal Eye Lesions

JACOVIDES (*Bull Ophthalmol Soc Egypt* 1937 30 34 174) states that 5 per cent of his menopausal patients complained of neuralgia, headache, vertigo, amaurosis, and loss of visual acuity. Three cases are fully described which typify the findings in such cases. They showed sluggish pupil reflexes, hyperaemia or ischaemia of the retina and disk, small retinal haemorrhages and inability to read even with glasses. The treatment employed was complete visual rest, dark glasses, a diet of milk and vegetables, ovarian hormone therapy, injections of strychnine, cocaine and adrenaline drops, and hot compresses.

The condition is attributed to the cessation in function of the ovaries. It should be remembered that asthenopia of accommodation may be due to cerebral tumours, syphilis, diphtheria or alimentary intoxication.

### 302 Dinitrophenol Cataract

W E BORLEY and M L TANTER (*Arch Ophthalmol* Chicago December 1937 p 908) using the capsules of ox lenses as permeable membranes for colloidal dyes in a series of experiments demonstrate that the permeability of the capsule in the presence of varying concentrations of dinitrophenol was very little altered. Similar investigation *in vivo* in rats led to the same result. They conclude that the existing evidence does not support the theory that dinitrophenol causes cataract by increasing the permeability of the lens capsule.

## Obstetrics and Gynaecology

### 303 Epithelioma of Bartholin's Gland

M CHATON (*Bull Ass franc Gynecol* December 1937 p 255) describes a case of epithelioma of Bartholin's gland, a rare condition of which only thirty cases could be collected by Harter in 1911. Chaton's case was that of a woman of 53 who had a tender swelling of the posterior part of the right labium majus. The right inguinal glands were enlarged and hard. The swelling was excised and on histological examination proved to consist of an enveloping shell of epitheliomatous tissue with a central centre. No glandular elements were seen in the centre. He maintains that the lesion was a primary cancer of the gland. No mention is made of any treatment of the enlarged inguinal glands but the patient is reported to have left the hospital cured.

### 304 Lipoid Nephrosis in Pregnancy

E ABUREL, I ORNSTEIN and C BART (*Pe franc Gynecol* January 1938 p 15) call attention to the relative frequency of the syndrome of lipoid nephrosis in pregnancy. They consider that pregnancy constitutes an important factor in the aetiology of this condition. Pure nephrosis is not associated with eclampsia nor with azotaemia or arterial hypertension. This pure form of nephrosis is rare in nephritis, the type usually being nephrosis associated with nephritic characters. It differs from nephrosis in the non-pregnant woman in that it is more resistant to treatment and usually persists for a long time after parturition. In this it differs also from the albuminuria of pregnancy. It may progress towards eventual cure or towards nephritis—a fact which renders prolonged post-natal care desirable.

### 305 Radium Treatment of Cancer of the Cervix

K SKAUM (*Norsk Mag Lægevidensk* February 1938 p 193) reviews the experiences of the gynaecological department of the Radium Hospital in Oslo where in the five-year period 1932 to 1937 852 cases of malignant disease of the female reproductive organs were treated. Cancer of the cervix was represented by 669 cases, cancer of the body of the uterus by 102, cancer of the vagina by thirty, cancer of the ovaries by twenty-two, cancer of the uterus and vagina by fourteen and chorion by five. As no case of cancer of the cervix was refused treatment and as there is still a marked tendency in Norway for surgeons to operate on early cases of cancer of the cervix and to treat early advanced cases into the Radium Hospital, his material was of a certain extent selected in an unfavourable way. Of 219 cases of cancer of the cervix treated at the Radium Hospital kept under observation for three years or more (11.25 per cent) were still alive after three years. With an 80 per cent

period of four and five years respectively the cases of cancer of the cervix still showed a symptom-free rate of about 42 per cent. In support of his claim that in Norway cancer of the cervix should be treated by radium and not by operation, the author confines himself to a three-year observation period, and classifies his patients according to the four recognized stages of the disease. Of the ninety-four patients in the first two stages (operable cases), sixty were symptom-free (64 per cent). The control cases were those from a gynaecological hospital in Oslo in the period 1906 to 1925. Of the patients operated on in this period in the first and second stages of the disease, only 33.5 per cent were symptom-free three years after operation.

## Pathology

### 306 Localization of Thrombosis

C PRIMA (*Zbl. Chir.* January 1, 1938, p. 21) discusses the conditions which determine the localization of thrombosis. It is well known that thrombosis of the vessels of the head, neck, upper limbs, and thoracic region is rare and occurs mainly in the condition known as thrombophilia. But the nearer the vessels approach the pelvis the more easily they thrombose, at the same time venous thrombosis is three times as frequent as arterial thrombosis. The conditions which determine thrombosis are to be found in the blood itself. The venous blood is more or less laden with toxic substances. This particularly applies to the portal system. Normally these substances are neutralized mainly by the ionized chlorine, which is supplied by the stomach and duodenum, but chiefly by the liver. In healthy individuals the portal blood is not much more toxic than the blood in the vena cava. But in cases of hepatic insufficiency the blood which reaches the right heart is charged with toxins, and may give rise to right auricular thrombosis, and, in extreme cases, to distant arterial thrombosis. The hypochloræmia which is produced by the increased demands on the chlorine reserves ultimately results in disturbances of the adrenal system and of the carbohydrate metabolism. The sympathetic disorder further aggravates the functional disturbance of the abdominal organs, with consequent stasis and accumulation of toxins in the portal system. This again favours the formation of thrombi wherever the portal blood meets the blood of the vena cava, as, for example, at the porto caval anastomosis formed by the inferior haemorrhoidal veins, which also communicate with the saphenous or the femoral vein. The special valves which normally prevent the backflow of the portal blood into the general venous circulation become insufficient in certain pathological conditions. The left femoral vein is particularly predisposed to thrombosis because of the extensive communication between the portal and general venous system in the region of the left sigmoid loop. This theory also explains why venous thrombosis in the upper part of the body is rare. Apart from the anatomical factors which determine the venous thrombosis there are also physical and chemical factors. The whirl which is formed at the junction of the two circulations, at different pressures, also favours thrombosis by causing a sedimentation of the thrombocytes and the formation of fibrin. Short-necked, muscular, and adipose individuals are particularly predisposed to thrombosis.

### 307 *Haemophilus influenzae* and Bronchitis

J. MULDER (*Acta med. scand.* 1938, 94, 1-2, 98) gives in account of his nine years study of acute and chronic diseases of the respiratory tract. Part of this study was conducted in the Dutch East Indies and part in Holland. As a rule, the clinical pictures in acute infections of the respiratory tract were identical in these two parts of the world. The *Haemophilus influenzae* represents, in the

author's opinion, a whole group of organisms, but in the present paper he refers to *H. influenzae* as a bacteriological entity which is to be found in the throats of 50 per cent of healthy persons. It occurs at all seasons, and in the Tropics as well as in Europe, and it is demonstrable in the mucopurulent sputum in cases of acute or chronic catarrh of the respiratory tract. Indeed, most cases of acute purulent tracheitis and bronchitis are, in the author's opinion, caused by it. It is, however, probably never alone responsible for lobar pneumonia. The susceptibility of healthy persons to infection with *H. influenzae* would seem to be very slight, and a high degree of susceptibility to it evidently depends on constitutional anomalies (exudative diathesis) and the debility associated with infancy, old age, operations, and exhausting infectious diseases. The author suggests that the frequent discovery of this germ in cases of influenza reflects the damage done by the virus of influenza to the mucous membranes of the respiratory tract, the resistance of which to the ubiquitous haemophilus group is impaired. The author adds that purulent or capillary bronchitis due to an infection with pneumococci alone must be very rare if it actually exists.

### 308 Systemic Affections of Cartilage

Apart from the well-known changes in rickets and arthritis deformans, H. v. MEYENBURG (*Schweiz. med. Wschr.* January 15, 1938, p. 57) describes, as maladies in which primary alterations of cartilage grossly affect the skeleton, (1) achondroplasia (chondro-dystrophia), (2) acromegaly, (3) a universal softening of cartilage—stated to be hitherto undescribed—of which a case is reported in detail. In the achondroplastic dwarf the skeletal changes are due to diminution of endochondral, with preservation of periosteal, ossification, the so-called periosteal fibrous strands, far from impeding endochondral ossification near the epiphyseal junction, mark the course of blood vessels which, near their anastomoses with those of the marrow, assist the deficient osteoblastic processes. The characteristic microscopic signs in cartilage have been found in a foetus of ten weeks, the offspring of an achondroplastic couple, the morbid condition is not of endocrine causation, but a disorder of growth. In acromegaly—as a result of over-production of growth hormone by eosinophil pituitary cells—the cartilage shows the opposed condition—namely, an exaggerated instead of a diminished endochondral ossification. Von Meyenburg confirms the recent findings of Erdheim concerning the chondral conditions in the acromegalic, even in maturity or old age the cartilage, especially in the ribs, intervertebral disks, and certain joints, shows proliferative changes such as were thought never to occur in the adult. Endochondral ossification is renewed, without or after preliminary calcification of the activated cartilage, and in addition the osteoblasts of the marrow are afforded material for the exercise of the bone-forming capacity which in their case normally persists through life. In the large joints the acromegalic cartilaginous changes begin in the deepest layers of the articular cartilage—a point which is clearly distinctive from senile or degenerative arthritic changes, which begin superficially. Proliferative changes have been discovered also in the laryngeal and tracheal cartilages in acromegaly. The author's case of generalized chondromalacia occurred in a boy, aged 14, and followed tonsillitis. Softening of laryngeal cartilages caused severe dyspnoea, and of articular cartilages swellings of the large joints. The roof of the nose sank inwards and the costal cartilages were softened, indented, and depressed, the trachea became a soft-walled tube. Microscopically the inflammatory nature of the chondral conditions was obvious, a vascular, highly cellular connective tissue penetrating the cartilages from both surfaces, no micro-organisms were found, and no signs of tuberculosis. Von Meyenburg, from his pathological observations, suggests a therapeutic trial in achondroplasia of purified hypophyseal growth hormone.

# STAPLES

"The finest Mattress made"

IT'S a private and personal pride to own the very best—To own a Staples Mattress—then no matter the day, the night is a time you look forward to—Hours of lingering luxury—Staples Mattresses are in the best private houses and most British Embassies throughout the world

## PALATABLE IRON

Ovoferrin Brand Colloidal Iron Tonic, iron in its most minute colloidal subdivision, is palatable, odourless, pleasant to take. It is ideal in pregnancy and in pediatrics. It will not stain the teeth, constipate or irritate the gastro-intestinal tract. We believe it to be the only hematinic simple enough, assimilable enough, agreeable enough for long term iron feeding. The adult dose is one tablespoonful in milk or water after meals and at bedtime. Prescribed in 11-ounce bottles. Write for free professional sample.

## TUBERCULIN PATCH TEST (VOLLMER)

*Bederle*

THE notable progress made in recent years in the control of tuberculosis has been due in large measure to earlier diagnosis and improved methods of diagnosis.

Among the significant advances in tuberculin testing is Vollmer's development of the *surrounding test*. This test, which has been borne out by clinical trial to be at least as reliable as the Pirquet test, possesses the important advantage of insuring co-operation of the patients, especially in the cases of children.

The patch is applied for 48 hours and read 48 hours later. By eliminating pain, elaborate preparation in the sterilisation of instruments, etc. trauma to the skin and other inconveniences attending the use of instruments, the performance of the test avoids alarming nervous patients.

The method is ideally suited to the testing of large groups. It is simple, safe and time saving. A local or general constitutional reaction has not been known to follow the application of the test. It is available for immediate use at a moment's notice.

TUBERCULIN PATCH TEST  
(VOLLMER) *Leads to* available in packages of 10 and 100 test

# Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil Blaud. The iron content remains fresh and unoxidized indefinitely and

injury to teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

# Iron Jelloids

You are cordially invited to apply for samples for clinical test

## OBSTINATE PSORIASIS RELIEVED ★

Often in spite of correcting faults of diet and clothing psoriasis proves obstinate. In such cases local treatment is indicated. Sphagnol Ointment (which contains soothing healing distillates of peat) will be found to be of assistance. It deals with the scaly eruptions and helps the growth of new and normal skin. Sphagnol Ointment, too, will be found

to be useful in the treatment of haemorrhoids and eczema.

In case you have had no personal experience of Sphagnol we shall be pleased to send you a clinical size sample for testing if you will write to Peat Products (Sphagnol) Ltd, Dept BMJ2, 21, Bush Lane, London, E C 4.

STOCKED BY ALL THE LEADING WHOLESALE HOUSES IN SOUTH AFRICA, CANADA, AUSTRALIA, NEW ZEALAND, INDIA, U.S.A.

IN CASES OF CHEST COLD, BRONCHITIS, ASTHMA, WHOOPING COUGH, SPASMODIC CROUP, and similar respiratory affections, Vapo-Cresolene brings relief. The germicidal vapour clears air passages and soothes paroxysms. Used at night during sleep it helps the patient to obtain undisturbed rest. Vapo-Cresolene is specially prepared from creosoles of coal tar and has a reputation of 57 years standing. It is invaluable for the treatment of children. Laboratory tests by a research laboratory of unquestioned standing, show that the vapours produced from Vapo-Cresolene by the Cresolene Vaporiser exert a direct germicidal action when in contact with moist surfaces harbouring pathogenic bacteria associated with respiratory affections.

# MAXADE FOCUSSED TONE

## *conquers deafness*

Some of the most stubborn cases of deafness have been relieved by Maxade Hearing Aids, after many other appliances have been tried without success. Practitioners and aurists tell us time and time again that Maxade Focused Tone has the power to overcome the handicap in almost all its forms. This simple feature enables pitch and volume to be adjusted by the user to suit exactly the individual degree of deafness. It is the nearest approach to natural hearing yet devised.

Any model will gladly be supplied for free clinical test. Maxade is entered upon the Approved List of the National Institute for the Deaf and consistently recommended by the principal hospitals. Details from Mr W. Scott Worthington, F.R.S.A., Peto Scott Co., 77, City Road, London, E.C.1 (Acoustical Engineers since 1919).

The range of models all most moderate in price, includes types with carbon or crystal microphones and with two or three stages of valve amplification ear pieces to choice. Pocket Model S2 P.L. illustrated.

*It enables me to join in the general conversation at home which I have not been able to do for 25 years writes Mr P. B. Upper Sydenham. Without the Aid I should not have heard a sound.*

## *Efficient and Effective Support*

### **SCIENTIFICALLY Applied**

The secret of the success of the Curtis Abdominal Support No. 1 lies in its scientific application of power. At all times it gives even anterior posterior pressure without undue constriction of the lower abdomen. The resulting support obtained allows for greater freedom and comfort than ever before. Medical men prescribe the Curtis Model No. 1 for all forms of abdominal ptosis—visceroptosis, enteroptosis and gastropptosis, and it is also recommended for support of ventral hernia and scar tissue in the lower abdomen.

## G.W.R. Travel Facilities for the Conveyance of Invalids

The Great Western Railway Company offer excellent facilities for the conveyance of hospital patients and other invalids.

Patients can make a throughout journey on the Company's new type of stretcher which very materially adds to the comfort of invalids who have to travel lying down.

The Company also have well appointed invalid saloons fitted with special couches suspended between the roof and floor to prevent oscillation bedding being provided where necessary. The invalid saloons also contain arm chairs, settees and table.

Meals are obtainable in most cases invalid chairs are available and every assistance is rendered by the Company's staff.

Full details of these facilities may be obtained from the Superintendent of the L.N. G.W.R. Paddington Station or from any G.W.R. Station Master.

When you  
prescribe Numol  
- your patient gets  
the maximum  
number of body-building  
units per teaspoonful.

Numol is a concentrated source of elements proved by scientific test and experience to be beneficial to weakened nerves and constitutions. It is definitely all that, but not merely that. It has a high content of all the vitamins other than the anti-scorbutic and has been submitted to the most rigid tests.

Numol provides in a highly concentrated form all those body-building elements which the Physician seeks and the debilitated patient requires, and just now when we are passing from a long tiresome Winter the patient who is recovering from an illness and little children who have weathered the Winter badly will all get on to their feet again more quickly with the help of a course of Numol.

Doctors are invited to write for a free jar.

### Fisher's Bastion Budapest Spa

A delightful scene bring  
ing to mind maybe many a happy  
day during a well earned rest.  
And talking of travel may we suggest  
to practitioners when next this subject  
looms on the horizon that whether  
they are themselves taking a holiday  
for pleasure or recommending their  
patients to take one for health  
The World wide Service of Cook's  
is at their disposal giving sound  
advice on all phases of travel  
handling all those worrying details  
that can so easily mar the enjoyment  
of a holiday  
Advice without obligation from any  
branch of

# *The Hearing Aid Par Excellence!* **BONOCHORD**

BONOCHORD High Fidelity Amplifiers are preferred by all who demand the best obtainable in hearing aids.

Here is a new model which can be worn on the person while in no way sacrificing the high quality of reproduction for which BONOCHORD Amplifiers are recommended by medical men.

Frequency response is from 200 to 8000 cycles per second. A Piezo electric microphone and three stages of amplification are employed also automatic volume control and noise-suppression. The aid is entirely dry battery operated with flash lamp cells for low tension which are obtainable everywhere.

All models are available for home trial. Any BONOCHORD instrument will be sent for clinical test free of charge on request. Send for the BONOCHORD booklet *The Hearing Aid Par Excellence* giving full details, illustrations and prices of all models.

## We Suggest that You Recommend THE ORIGINAL PINEAPPLE JUICE FROM HAWAII

THIS appetising fruit juice from Hawaii offers a sparkling change from routine fruit juice menus. Children especially like it. Because it is assimilated so easily it is ideal for babies. That is why, when your patients ask your advice about fruit juices, we suggest that you recommend Dole—the original Hawaiian pineapple juice. This delicious, golden juice is sealed in tins by the exclusive Dole Fast Seal Vacuum Packing Process. That is why Dole Pineapple Juice retuns, in high degree, the fresh fruit constituents of ripe pineapple, as well as the fragrant, field fresh flavour. Also it is a natural source of vitamins A, B, & C. J. K. Husband & Co., Ltd., 10 Eastcheap, London, E.C.3

### Here is a typical Analysis of Dole Pineapple Juice

Moisture	85.39%
Ash	0.1
Fat (ether extract)	0.3
Protein (N x 6.25)	0.3
Crude fibre	0.02
Titratable acidity as citric acid	0.9
Reducing sugars as invert sugar	12.4
Carbohydrates other than sugars (by difference)	0.38

**THE SURF RIDER**—Surfing, the sport of Hawaiian kings in olden days, was one of the favourite pastimes. Owing to the way the surf breaks on the reef, Waikiki is the only place in the world where this sport is indulged in under ideal conditions.

It is a marvellous sight to see the upright gleaming brown bodies of the native surfers come riding swiftly shoreward on a giant comb.

**P.S.** Just write to us on your letterhead and we will be pleased to send you free a sample tin of delicious Dole Hawaiian Pineapple Juice.

**ANAHÆMIN B.D.H.**

*In sub-acute combined degeneration of the cord*

Reference has recently been made (Goulstonian Lectures, 1938) to the value of Anahæmin in sub-acute combined degeneration of the cord. Dosage which is adequate for the treatment of pernicious anæmia, as indicated by the maintenance of a red blood cell count of 5,000,000 or more, is effective in preventing the onset of symptoms of sub-acute combined degeneration of the cord. In the treatment of this condition, however, two or even

three times the normal dosage of Anahæmin required for the treatment of pernicious anæmia may be necessary.

No undesirable effects have been reported following the administration of such abnormally large doses of Anahæmin, and it is accordingly recommended that, in order to prevent the onset of symptoms of sub-acute combined degeneration, dosage should in all cases be such as will ensure that the red blood count does not fall below 5,000,000.

'AMYTAL'

BRAND

*Iso-amyl Ethyl Barbituric Acid***FOR SEDATION AND HYPNOSIS**

● The tranquil sleep of children is always the envy of less fortunate adults to whom at times this boon is denied because of sickness or other conditions which upset the psychic or emotional equilibrium

'Amytal' supplies the relaxation and sleep which are essential to recuperation of vital forces. It may be prescribed wherever there is need to combat insomnia, restlessness, or apprehension. A noteworthy margin of safety is characteristic of 'Amytal,' and since destruction of the hypnotic within the body appears to be accomplished rapidly there is little tendency to unwelcome side-reactions or after depression.

'Amytal' is supplied in  $\frac{1}{2}$ -grain,  $\frac{3}{4}$ -grain, and 1 $\frac{1}{2}$ -grain tablets in bottles of 40 and 500.

# OESTROFORM

## For Relief of Menopausal Symptoms

Oestroform is an ester of the pure oestrogenic hormone standardised in International Benzoate Units. It possesses a specific action in the treatment of symptoms associated with the menopause.

Injections of Oestroform 20 000 or 50 000 I.B.U. according to whether the condition is moderate or severe should be administered twice weekly for three or four weeks until the symptoms have been brought under control. If the patient is still menstruating treatment should be confined to the first half of the intermenstruum, when menstruation has ceased treatment may of course be continuous.

As soon as alleviation of symptoms has been attained dosage should be reduced the object of treatment being not to postpone the onset of the menopause indefinitely but merely to keep the distressing symptoms in abeyance and to allow the patient to become adjusted gradually to the endocrine changes which are taking place.

Eventually it may be found that the oral administration of Oestroform tablets alone three of 1 000 I.U. daily may be sufficient to maintain the patient's hormonal level adequately.

## the prevention of infection —

It is now generally agreed that

*deficiency of the vitamin B complex  
may be related to increased susceptibility  
to certain kinds of infection*

(Proc. R. Soc. Med. 1937 30 1037)

A popular method of raising the vitamin-B content of the diet consists in the systematic administration of Marmite. This yeast extract is rich in all the vitamins of the B group and is being increasingly prescribed for its health promoting properties.

Marmite is ordered as a routine measure all the year round in private practice and in hospitals, schools and welfare centres, and when epidemics prevail its use is especially indicated. On account of its appetising flavour Marmite is appreciated by patients of all ages but children find it a particularly attractive dietary adjunct.

in preventive and curative medicine and in convalescence

## To prevent complications in Gonorrhoea

### ARGYROL

BRAND SILVER VITELLIN

"STRONG ANTISEPTICS not only fail to control the infection but actually increase the inflammation and stimulate bacterial activity by virtue of the tissue trauma which is thus introduced"

\* So writes a noted urologist in discussing the prevention of complications in gonorrhoea

Frankly, Argyrol is not a strong antiseptic in the test-tube, in the infected urethra, however, because of its unique mildness and sedative effect, Argyrol not only destroys the surface gonococci but stimulates healthy tissue reaction and hastens normal restitution. Which means a cure without complications. Thirty-six years of satisfactory service in the treatment of gonorrhoea has made Argyrol the standard therapy throughout the world.

It should be emphasized that Argyrol is not just another "mild silver protein". It is different because its constituent elements are different.

Argyrol is in a class by itself—*sur generis*. It has never been duplicated and it is the only silver salt which does not become irritating with increased concentrations.

Insistence on having the name ARGYROL on all solutions ordered or prescribed, will ensure the clinical results you expect.

## RADIOSTOLEUM EMULSION WITH VITAMIN C

The difficulty experienced in the administration of Vitamins A and D in the form of an oil and Vitamin C in the form of orange juice to infants, whether breast-fed or bottle-fed, is obviated by the use of Radiostoleum Emulsion with Vitamin C. It mixes readily with the feed of the bottle-fed infant, or it can easily be given direct from a spoon. Each tea-

spoonful contains 6000 international units of Vitamin A, 200 international units of Vitamin C and 1200 international units of Vitamin D.

Samples for clinical trial are available on request.

Radiostoleum Emulsion with Vitamin C is issued in bottles containing 4 fl. oz. at 2/6 per bottle.

# To give you a better

# Therapeutic

# result...

In the treatment of all debilitating conditions and in diseases of malnutrition the foremost authorities are agreed that the source of radiation should as near as possible approximate the U V wavelengths found in the Solar spectrum. The shorter or non-terrestrial wave-band merely brings about a too rapid erythema before the longer and essential wavelengths have become fully effective. In the "BIOSOL" the wavelengths below 2900 AU are completely cut off by means of the "DORNO" filter. When on the other hand a strong erythema is required—as in the treatment of skin diseases, the "DORNO" filter (exclusive to the "BIOSOL") has only to be removed. In this way provision is made for the two wave bands which correspond to the two classes in which cases for actino-therapy can be roughly grouped. The "BIOSOL" thus rationalizes technique to quite a new degree and is the obvious choice for a modern clinic.

## For the EARLY PREVENTION OF VITAMIN & MINERAL DEFICIENCY IN INFANTS

It is now a widely recognized fact that infants need vegetable food as early as possible in order to balance and augment the usual milk diet. The difficulty, hitherto inseparable from vegetable in any form, has been the intestinal disturbance—notably diarrhoea—of which inability to digest the tough fibrous tissue surrounding the food cells is the primary cause.

By the Libby process of Homogenization this fibrous covering is broken up into fine particles which provide non-irritant bulk and smooth, easy elimination. The nutriment is of course at the same time released so that it comes into direct contact with the digestive enzymes.

There are six scientifically formulated combinations of Cereals, Vegetables and Fruit in Libby's Homogenized Foods which can be prescribed in any case where Vitamin and mineral deficiency is indicated, and have been given successfully to infants as young as 12 to 8 weeks.

A partial analysis of one combination, set out in the table below, shows how the deficiencies in any one vegetable are compensated for by the values in the others.

PARTIAL ANALYSIS OF A GROUP OF VEGETABLES

	Spinach	Carrots	Peas
Protein	2.1	1.1	3.6
Fat Per Cent	0.3	0.4	0.2
Carbohydrates	3.2	9.3	9.8

# Oral Vaccine for the prevention of Colds and Influenza

Since Genosol brand Oral Vaccine was introduced to the Medical Profession last Winter, extensive clinical and laboratory tests have shown that it establishes a high degree of immunity against colds and influenza, the oral vaccine has also proved successful in the treatment of chronic bronchitis and similar respiratory infections.

This vaccine contains hemolytic streptococci, in addition to other organisms incriminated in the causation of colds and influenza infections. It has been found that the ingestion of the oral vaccine against colds and influenza also develops immunity to diseases caused by hemolytic streptococci.

Particulars concerning Genosol brand Oral Vaccine will be found in the new brochure on Vaccine Therapy which has recently been published by Genosol Ltd. This booklet also gives information regarding a wide range of vaccines administered by hypodermic injection and the standard types of Local Immunity Products. A copy of the brochure will gladly be supplied to any physician on request.

## Better Salicylate Therapy

**W**HATEVER be the season of the year, there is a wide sphere of utility for "Alasil," the improved form of salicylate medication

"Alasil" is a very definite advance on ordinary compounds of salicylic or acetyl-salicylic acid both in therapeutic efficiency and in freedom from the risk of unpleasant gastro-intestinal sequelae. This high tolerability is due to the fact that "Alasil" is composed of calcium acetyl salicylate—the least irritating of the salicylate compounds—and "Alocol" (Colloidal Hydroxide of Aluminium), a powerful gastric sedative and antacid.

A careful series of experimental tests has shown that "Alasil" is more completely absorbed than ordinary salicylate compounds and that it is practically free from the risk of liberating free salicylic acid in the stomach.

Wide clinical experience anticipated these findings by demonstrating that "Alasil" can be pushed or prolonged to a much greater extent than ordinary salicylate compounds and that it can be given with safety to children, adults, the aged, and patients with finely-balanced digestive capacities. An analgesic, antipyretic and sedative of established value.

## Effective in Nervous Dyspepsia

**W**HATEVER be the fundamental cause of nervous dyspepsia, it is acknowledged that alleviation of the gastric symptoms is an important part of effective treatment.

Nervous dyspepsia connotes hypersecretion. This causes flatulence, sour stomach, discomfort, and perhaps pain. 'Alocol' provides the ideal gastric sedative since its action is prompt and lasting and entirely free from harmful effects.

'Alocol' acts by adsorbing excess of free hydrochloric acid in the stomach, forming a colloidal jelly which passes through into the intestines and is finally evacuated. 'Alocol' therefore actually removes from the system the causative radicle (Cl) instead of merely temporarily neutralizing it. 'Alocol' does not interfere with normal digestion, nor does it determine any unpleasant secondary reactions. It is issued in tablet and powder form.

*Complete chemical history of "Alocol" with concluding clinical reports and supply for trial sent free to physicians on request*

# Disease-emaciation

"EVERY medical practitioner knows how difficult it is to nourish a patient suffering from disease emaciation. Do we not all recognise the fact that the starving tissues are fed, not by the food swallowed by the patient, but by the amount of nutrient matter absorbed by the gastric and intestinal mucous membrane? If we could ensure the absorption of nutriment into the blood, the problem of nutrition in disease would be reduced to a matter of mere chemistry and mechanical feeding. Judging from clinical results, 'Sanatogen' appears in many cases to possess some power of ready absorbability, without which the richest foodstuff represents simply so much foreign matter in the stomach and intestines. My own experience of 'Sanatogen' is that it staves the diarrhoea—ten or twelve motions a day are thereby reduced to one or two, it stops vomiting, and it improves general conditions and causes the patient to put on flesh."

NUTRITION IN WASTING DISEASES OF CHILDREN AND ADULTS

(*Medical Press and Co. Ltd.*)

"THIS condition, which results from imperfect digestive or absorptive power or which may follow stomatitis, pyloric stenosis, deformity of the tongue or palate, tuberculosis or syphilis, is most frequently associated with improper feeding. Fats in such cases are not well tolerated, but the contrary is true with respect to proteids. The use of 'Sanatogen', in these cases, proved so satisfactory that we have been encouraged to try it in other cases of infantile atrophy and have had almost equally pleasing results in a number of patients suffering from this condition. It is quite apparent that 'Sanatogen' has considerable power in influencing nutrition."

"INFANTILE ATROPHY"

(*Practitioner*)

"I HAVE before me the records of forty cases fed with 'Sanatogen'. They show what was obvious to myself and the nurses when watching the cases that these patients wasted less during the acute stage, and picked up more rapidly during the convalescent stage, than patients who did not have 'Sanatogen'. This fact indeed was soon recognised by the ward sister without my having in any way drawn her attention to it."

I am firmly convinced that it is a most valuable food for the typhoid patient.

# OSTERMILK

NUMBER NUMBER

**1 & 2**

Ostermilk dried milk foods No 1 and No 2 vary in composition to meet natural development in the digestive capacity of the bottle-fed infant. Ostermilk No 1 contains less protein and fat and its digestion therefore is within the competence of the new-born infant. This modified food is recommended for use until the infant reaches the age of three to four months (or, calculating by weight, 10-14 lbs.)

Thereafter, the full fat and protein dried milk product—Ostermilk No 2—is preferred as the

complete milk food suitable for older infants. Both Ostermilk No 1 and No 2 are enriched with the protective vitamin D and also with iron (each in measured amounts). One-sixth of the babies of England are fed on Ostermilk and its popularity with doctors and mothers alike pays tribute to its sound growth-promoting and health-producing qualities.

Ostermilk maintains the high standard of all G.L. products at a price that makes it available, through chemists, to every class of patient.

## Response to Minadex observed in over 1,000 Children convalescent from fevers

In 6 oz bottles, 2/6 12 oz 4/6, 80 oz tins, 22/6  
Less usual discount. These prices do not apply in Eire.

SYRUP MINADEX enables practitioners to give one tonic where two were needed before. It combines, in one effective and pleasant preparation, the active principles of both *Syr Ferri Phosph Co* and *Cod-Liver Oil*, together with reinforcing "trace" minerals.

At a leading London fever hospital Syrup Minadex is employed as the sole tonic for the children's wards. In two years over 1,000 children have received it there and a testimony\* demonstrates how valuable a part of the ward routine it has become.

Any child not eating well—straight on to Minadex. That is now their rule. "The speedy way in which Minadex restores appetite is quite remarkable. And the evident enjoyment of Minadex by all children bears full witness to its acceptable flavour. A much larger dose of iron can be tolerated by children when given as Syrup Minadex and, contrary to expectation, Minadex

is slightly laxative. We consider ourselves fortunate to have found a tonic so safe that we can prescribe it for every case from whooping cough to measles, even at the acute stage.

"Always can we be confident that Minadex will have a dependable re- to active effect."

## ON THE ORIGIN OF CANCER\*

BY

W. CRAMER, Ph.D., D.Sc., M.R.C.S., L.R.C.P.

(From the Imperial Cancer Research Fund)

Why does a patient get cancer? That is a question which summarizes the problem of cancer and which must have often occurred to you when a patient presents himself or herself apparently in good health except for some obscure and not necessarily painful symptoms and on examination a malignant growth is found sometimes in an early stage but possibly already in an advanced stage although the patient may have presented himself as soon as he noticed that something was wrong. It is this insidious onset of cancer—striking a patient like a bolt from the blue—which has given the disease the air of a grim mystery.

### Interpretation of Age Incidence

If I were asked in what respect the experimental investigation of cancer of the last fifteen years has most profoundly altered our outlook on the cancer problem I would say it lies in the correct interpretation of the age incidence. The frequency of cancer increases with increasing rapidity as age advances. This can be readily seen from the following table which gives the mortality rate per million people from cancer of all sites in decennial age groups in England and Wales.

Age Groups	0-	15-	25-	35-	45-	55-	65-	75-
Cancer Mortality Rate	52	41	140	596	1,593	7,390	21,711	127,077

The death rate from cancer increases in almost geometrical progression. I know of no other disease which exhibits a similar phenomenon. This remarkable feature of the disease must therefore have a fundamental significance.

Formerly the insidious onset of cancer—the bolt from the blue—led us to believe that the origin of cancer begins with the first appearance of a malignant cell. This as will be discussed presently is due to an intracellular change by which a normal cell becomes transformed into a malignant one and our attention was riveted to the investigation of this change as the one and only problem concerned in the aetiology of cancer. The fact that cancer occurs much more frequently in old people than in young or even middle aged people was explained formerly by the assumption that the senility of the tissue is the predisposing factor in the origin of cancer. It was believed that in such senile tissue cancer arises suddenly. But the experimental investigation of cancer has shown clearly that it can be induced in a young or middle aged

organism as readily as it not more readily than in an old one and further that when cancer has arisen the malignant cells soon grow in a young organism as readily as it not more readily than in an old one. This rules out senility as a direct aetiological factor in cancer.

### Carcinogenic Agencies

When it became possible to induce cancer experimentally it was found that there are a great many different agencies capable of inducing cancer in such a tissue as the skin. Chemical substances such as tar or the pure organic substances synthesized by Kernoway and Cook, physical agencies such as light rays and radium rays, heat and even gross parasites.

All carcinogenic agents have this in common that they induce cancer only after a lapse of time occupying a considerable fraction of the normal span of life characteristic for each species and furthermore that this period of induction is much more prolonged with a weak carcinogenic agent than with a very active one. We have learned further that during the prolonged action of these carcinogenic agents the tissue on which they act undergoes pathological changes and that cancer arises within this altered tissue. Now in man the bulk of cancer patients belong to the last half—even the last third—of the normal span of life. We can therefore conclude that in man cancer arises as the result of carcinogenic stimuli acting over a prolonged period occupying a considerable fraction of the span of life and it is so it follows further that cancer does not appear as a bolt from the blue in a healthy tissue but that as a result of its prolonged action of a carcinogenic agent the tissue or organ on which it acts undergoes pathological changes before cancer develops. That the preceding existence of such precancerous conditions was not generally—and still is not generally—recognized is due partly to the fact that the need not be sufficiently severe to manifest themselves as a definite disease especially when they develop in tissues or organs which are not readily accessible to clinical examination. They have however long been recognized in the skin where the whole course of carcinogenesis is visible. The term "precancerous condition" was in fact coined forty years ago by dermatologists as the empirical result of clinical observations.

### Two Phases of Development

We see then that the development of cancer whether it arises spontaneously or whether it is induced experimentally presents two phases. The first phase is a long

preliminary one which we may call "*the origin of cancer*" This extends over a long period of years amounting to a considerable fraction of the span of life—hence the characteristic age incidence of cancer—and it culminates in the sudden transformation of a few normal cells into malignant ones. During that phase in a more or less extensive though localized area of tissue a pathological condition develops, characterized by increased cellular proliferation in which subsequently cancer arises in a single cell or a small group of cells. The development of this precancerous condition depends upon the action from without on the cells of a given tissue of agencies of the most diverse nature—agencies which are called carcinogenic agencies. Carcinogenic agents may be substances foreign to the body acting locally where they are applied, they may be abnormal metabolites acting locally, or they may be formed in the body as normal metabolites—for example, oestrone, a hormone formed by the ovary but which produces its carcinogenic effect not on the cells where it is formed but on the cells of another organ remote from its origin—the mamma. But I emphasize the statement that during this preliminary phase the cells are being subjected to agencies acting on them from without.

Now the scene changes from the environment of the cell to its interior. When a cell within a precancerous area undergoes the transformation into a malignant cell a new race of cells arises. A change occurs *within* the cell which confers upon it the biological behaviour by which we recognize malignant cells and by which malignant cells kill the organism in which they have arisen. This biological behaviour characteristic of a malignant cell is its autonomous growth.

We pass now to the *second phase* of our problem—the *growth of cancer*, and I wish to emphasize that there is an essential and fundamental distinction underlying the mental concept of these two phases as two distinct and separate problems. The problem now is: What is the nature of the difference between the normal cell and the cancer cell? This difference does not consist, as is sometimes stated, in the acquisition of the property of growth. For the normal cells of the epithelium of the skin or of the intestine, of the lymphatic tissues, of the blood-forming tissues, and particularly of the cells of the embryo, all have this power to grow—that is, to form new cells. But this normal growth is subject to inhibitory and stimulating influences which regulate it in such a way as to ensure the well-being of the whole organism. The cancer cells are no longer subject to these stimulations and inhibitions. They are a new race of cells. They grow—that is, they multiply—sometimes rapidly, but sometimes very slowly, but always without any regard to the physiological needs of the tissue in which they have arisen and without regard to the physiological boundaries imposed after the growth of normal cells. By their destructive autonomous growth in a vital organ they kill the organism in which they have arisen. When a malignant tumour has appeared, either spontaneously or by experimental procedures, the cells of this tumour will continue to grow and form new tumours when placed into other perfectly normal animals. They can be kept growing *ad infinitum* by successive transplantations into normal animals in a perfectly normal environment and without any further application of the carcinogenic substances which have brought about their appearance.

Summarizing these experimental facts once more we can transform a normal cell into a malignant cell by acting on it from *without* the cell, this phase represents

*the origin of cancer*. But when this transformation has once occurred the malignant cell pursues its course in the absence of any agent acting on it from without. We are faced now with the problem of the *growth of cancer*. Whatever it is that drives the cancer cell on in its autonomous growth must reside within that cell, and that intracellular change is irreversible. The investigation of this second phase of the cancer problem is clearly much more difficult than that of the first phase. For our concern is now with subtle problems of cellular pathology, where even a rudimentary knowledge of cellular physiology is lacking. Essentially our task in investigating the growth of cancer is to search for differences between normal and malignant cells.

But it is not sufficient to discover differences, for these might be not the cause but the effect of the abnormal behaviour of malignant cells. It is necessary to establish differences which can account for the characteristic biological behaviour of malignant cells.

### Growth of Cancer Two Conceptions

Numerous attempts have been made to explain the growth of cancer by highly speculative conceptions. I shall content myself with mentioning very briefly two conceptions which are founded on a basis of experimentally established facts—namely

1 That the intracellular change is represented by an alteration in the metabolism of the cell in such a way that it enables the cancer cell to obtain the energy necessary to maintain its life by a process of fermentation—that is, a process which does not require the abundant supply of oxygen required for the maintenance of life of the normal cell.

2 That the intracellular change is due to the presence of virus.

These two conceptions must not be regarded as mutually exclusive theories, but as working hypotheses having as their object to elucidate from different angles the autonomous growth of the malignant cell. Thus it is by no means unlikely that the presence of a virus within a cell might alter the metabolism of a cell, and it has in fact been found by Crabtree that in certain virus diseases, such as fowl-pox and vaccinia, in which there is a temporary cellular proliferation, the metabolism is similar to that characteristic of malignant growths. As this lecture is concerned with the origin of cancer, I must refrain from a discussion of these two conceptions. A detailed exposition of the conception of a virus being responsible for the growth of malignant cells has been given in recent years in papers by Peyton Rous and by W. E. Gyac. But the conceptions which I mentioned are working hypotheses, and if they are to be judged, as working hypotheses should be judged, by their results, they have been most fruitful.

What interests us from the point of view of the origin of cancer is the question how these conceptions are to be reconciled with the long preliminary phase necessary for the development of malignancy. That a fundamental and permanent change in the metabolism of a cell requires a long period of adaptation to abnormal conditions can be expected *a priori*. Less obvious is the explanation why a long preliminary period is necessary to enable a virus to enter a cell and transform it into a malignant one.

### The Virus Hypothesis

The conception of a virus being responsible for the autonomous growth of cancer has met in the past with a strong opposition. This is due mainly to the fact that

most of the viruses with which we are familiar are the causes of highly contagious diseases such as small pox, measles and foot and mouth disease. But it is not an essential feature of a virus infection to be contagious any more than it is an essential feature of a bacterial infection. A virus is by definition a particulate pathogenic agent capable of multiplying foreign to the organism and of a uniform size which is below the limit of microscopic vision but above that of the largest organic molecule known to exist in the normal cell.

It is clear that the conception of a virus in the cancer cell cannot alter the clinical features of the disease but must adapt itself to them. Cancer is not a contagious disease. Even the towel tumours in which a virus can be demonstrated are not contagious. Assuming then for the sake of argument that the growth of all malignant cells is due to a virus, how could we correlate this with the established facts concerning the aetiology of cancer such as the existence of a long preliminary phase or the characteristic age incidence which is the statistical expression of this preliminary phase?

If we produce a tumour in the skin of a mouse by dibenzanthracene or in the mamma of a mouse by painting the skin with a chlorotorm solution of oestrin we clearly do not introduce thereby a virus. The virus must therefore have been pre-existent in the animal in a non-pathogenic condition. And since such tumours can be induced in a high percentage of animals these viruses must be frequently present in a non-pathogenic condition. The treatment with dibenzanthracene or oestrone respectively would then appear to play the part of so altering the cells that the virus becomes pathogenic for them. This is by no means an extravagant assumption to make for even with bacterial diseases there are well known examples where either bacteria or their spores remain non-pathogenic but become pathogenic when the tissues are subjected to abnormal conditions. The point I wish to make here is that even if the growth of malignant cells were due to a virus the prolonged preliminary phase in which the tissue undergoes a pathological alteration—the precancerous condition—would still remain a determining factor in the aetiology of cancer.

Quite recently Dr Peyton Rous has published an account of experiments which illustrate this relationship in a very striking manner. There exists in rabbits an infective papilloma of the skin—which is due to a virus—the so-called Shope papilloma. This papilloma can be transmitted to other rabbits by introducing cell free material obtained from such a papilloma into the scarified skin of a normal rabbit. After two weeks a papilloma begins to appear which may grow for several weeks and eventually regress or it may continue to grow and form large masses. After an interval of many months a malignant tumour sometimes develops underneath such a papilloma but no virus can be obtained from such a malignant growth although it is present in the papilloma. Rous subjected the ears of rabbits to tarring lasting over periods varying from two to four months. As a result a number of warts appeared on the skin. If tarring is now discontinued the warts as a rule disappear gradually and in order to produce a carcinoma in a rabbit tarring has to be carried on for eighteen months or more. But when Rous after two to four months tarring introduced into the tarred rabbits the virus from the Shope papilloma by intravenous injection the tar warts after an interval of three weeks—the incubation period of the virus—began to grow with explosive rapidity as if the virus had become localised in them and after one or two months true carcinomata of the skin developed in the tarred ears.

A similar experiment but with a different virus—the fibroma virus of Shope—has been carried out by Andrewes, Ahlstrom, Foulds and Gye. The fibroma virus ordinarily

produces fibroma like connective tissue swelling or subcutaneous injection into rabbits. These swellings eventually undergo spontaneous regression. But when this fibroma virus was injected intravenously into rabbits which had received previously an intramuscular injection of tar, connective tissue swellings appeared at the site of the injected tar and these swellings did not regress but grew progressively like true fibromata and in two cases growths arose which had the characters of true malignant new growths of the connective tissue.

Experiments such as these demonstrate very clearly the existence of the two phases in the aetiology of cancer: the preparatory action of the carcinogenic substance (tar) followed by the effect of the virus on the cells which had been prepared for its reception and in which the virus becomes localized.

### The Factor of Susceptibility

From the account which I have given so far it would appear that a malignant tumour develops whenever a carcinogenic agent is applied. But fortunately that is not so. I say *fortunately* because if my account was correct the incidence of cancer in man especially in people of 60 years and more would be much heavier than it actually is. The carcinogenic agents or stimuli are so numerous and various that it is difficult to see how one could avoid being exposed to them and cancer would then appear as a normal concomitant of old age like the greyness of hair or any of the other signs of old age. Fortunately the effect of carcinogenic agents is heavily conditioned by factors which reside within the organism and when we may group together under the term *susceptibility*. Ten years ago I drew attention to the significance of this factor by the following experimental observations:

If the skin of a large number of mice is subjected to a prolonged treatment with a weak carcinogenic agent, some mice will develop a skin carcinoma after about four months, others after six months, eight months, or even a year and some individuals will remain completely free from cancer. Since the differences are found while the animals are kept under identical conditions they must be due to a factor or factors of susceptibility intrinsic to the animals.

The importance of this factor has since been corroborated experimentally by another technique. In mice it is possible by prolonged inbreeding obtained by brother and sister mating to produce strains of mice in which the genetic constitution of the individuals belonging to a particular strain is very nearly the same. It is possible to breed such a strain from a cancerous ancestry; it is possible sometimes to obtain a strain of mice with a very high incidence of spontaneous cancer in one particular organ—most commonly the mamma. In such a strain only the females develop mammary cancer after they have passed a certain age. In this way strains have been obtained in which 70-80 and even 90 per cent of all the females develop spontaneously cancer of the mamma. Conversely it is possible to breed strains of mice in which the incidence of spontaneous cancer of the mamma in the female is very low and may even be zero. If from the males of such a strain are subjected to treatment with oestrogenic hormones it is possible to induce mammary cancer even in mice with the readiness with which they are reported to be free from mammary cancer in the different strains. In the same way it is possible to breed a strain of mice in which the females develop mammary cancer spontaneously the oestrogenic hormone may be completely unable to induce cancer although given over a much longer period and there is no further effect. Hence the origin of cancer is bound up with the susceptibility of the individual to the action of the carcinogenic agent.

Susceptibility is a deliberately vague term because our knowledge concerning it is as yet very incomplete. It comprises all those factors which condition the effect of the various carcinogenic agents. It may be concerned with the facility with which these agents induce the pre-cancerous condition, or again it may be concerned with the facility with which the malignant transformation sets in within such precancerous conditions. Dr E. Horning and I have shown recently, for a strain of mice with a very high incidence of mammary cancer, that the susceptibility to cancer of the mamma in this strain is due to an endocrine imbalance, particularly an imbalance between the oestrogenic hormone from the ovary and one or more hormones of the anterior lobe of the pituitary. Another important point is that an organism highly susceptible to the development of cancer in one particular tissue—the mamma—is not necessarily very susceptible to the development of cancer in a different tissue—the skin, for instance. In animals highly susceptible to mammary cancer the skin may, in fact, be resistant, and sometimes highly resistant, to the action of substances carcinogenic for the skin.

The conclusion we should draw from this line of work is that what is inherited is not cancer as a disease but a susceptibility to the development of cancer—that is to say, a tendency to respond with the development of cancer to carcinogenic influences which may be so weak as to be ineffective to the average normal organism—and, further, that this susceptibility is not a susceptibility to cancer generally, but is limited to one or at the most very few organs or tissues.

#### Remote and Proximate "Causes"

We have now completed our rapid survey of the origin and the growth of cancer.

It has been said by a distinguished physicist that problems are often found to be insoluble because they have been wrongly formulated. This is certainly true of the search for the *cause* of cancer. If I have been able to make myself clear to you, you will agree that the question, "What is the cause of cancer?" is meaningless. Does it refer to what I have called "the origin of cancer"—that is to say, the prolonged preliminary phase without which in the majority of cases cancer would not arise? Or does it refer to the growth of cancer—the sudden intracellular change which confers upon the malignant cell its power of autonomous growth and of metastasizing? They represent, as I have said before, two entirely distinct problems. If we wish to adhere to the use of the term "cause," we may distinguish them by calling the one the *remote causes*—that is, the origin of cancer (and these comprise not only the carcinogenic agencies but also the factor of susceptibility), and the other the *proximate cause*—that is, the growth of cancer. If we take as an example the skin, where the aetiology of cancer can be studied most readily, we know that cancer of the skin can be "caused" by, *inter alia*, light, x rays and radium rays, contact with tar, with certain organic hydrocarbons, and with certain lubricating oils. Here there are six different remote causes of skin cancer. They all lead up to the intracellular change, which we may assume is the same whatever the remote cause may have been, since malignant tumours produced by one carcinogenic agency, though differing *inter se*, do not essentially differ from malignant tumours produced by any of the other carcinogenic agencies. We may assume, then, that the growth of cancer of the skin is the same, no matter what the origin may have been, and, further, that the growth of cancer is the same for all organs and tissues, no matter what

the origin may have been. But we should always bear in mind the mental reservation that this unity of the proximate cause is an assumption which we can only accept so long as there is no evidence to the contrary.

We see, then, that cancer from the point of view of the proximate cause—that is, its growth—may be regarded as a single disease. But from the point of view of the remote causes—that is, its origin—cancer is a multiplicity of diseases. From this second point of view each tissue has its own specific aetiology, different from that of other tissues, and we must even go further and admit that there may be different remote causes for each tissue. I have just given an example by referring to a number of remote causes of skin cancer. My colleague, Dr Horning, and I have been able recently to bring evidence to show that cancer of the mamma can be due to—or, as I should say, has for its remote cause—an endocrine imbalance between the ovary, the pituitary gland, and possibly, also, the adrenal gland. But it does not follow that this applies to all cases of mammary cancer.

We should therefore discontinue the search for the cause of cancer, which is based on a naive and crude simplification of the problem, and substitute for it the exploration of the causation of cancer, bearing in mind always that this comprises the two separate and distinct conceptions of the origin and of the growth of cancer.

#### Experimental Analysis of Carcinogenesis

In the experimental analysis of carcinogenesis we have now reached a point where the two factors—carcinogenic stimulus and susceptibility—can be introduced into the experiment in almost quantitative doses. Their relationship can be expressed, though somewhat crudely, by a simple equation applying to two known and measurable variables, A and B, and a constant, C, where A is the carcinogenic stimulus and B the susceptibility, while the constant C represents cancer. The equation is  $A \times B = C$ .

In that equation an increase in A involves a diminution in B, and vice versa—that is to say, the aetiological importance of the factor of susceptibility increases as the strength of the carcinogenic agent or stimulus diminishes. A weak carcinogenic agent which will elicit cancer readily in a highly susceptible individual will remain ineffective in an individual with a lower susceptibility, and where the susceptibility is very low even a strong carcinogenic stimulus may be ineffective. Moreover, when cancer develops in response to a carcinogenic stimulus applied to individuals of different levels of susceptibility it will develop more rapidly in those with a low susceptibility than in those with a high susceptibility.

Under experimental conditions we can therefore predict whether an animal will or will not get cancer of the mamma by controlling the two factors—carcinogenic stimulus and susceptibility. The carcinogenic stimulus is a pure chemical substance—oestrone—which can be given in accurately measured doses, while susceptibility can be varied by using different inbred strains of mice with a known incidence of spontaneous cancer of one particular organ.

#### Applications to Cancer in Man

When we try now to answer the question with which I opened this lecture—"Why does a patient get cancer?" by transferring these findings and conclusions to man, we meet at once with the difficulty that the two factors—susceptibility and carcinogenic stimulus, which under experimental conditions were variable and known, now are variable but unknown. The equation reads now  $X \times Y = C$ .

We know that the patient has cancer and our task now is to search for shreds and patches of evidence concerning the part played by susceptibility and concerning the nature of the carcinogenic stimulus. This is clearly a difficult task. But it has to be faced if the advance in our knowledge of cancer obtained by the experimental study in animals is to lead to a control of the disease in man. That it is not an impossible task is shown by the knowledge obtained in recent years.

The part played by the factor of *susceptibility* has been made evident by the recent statistical investigations of Wasink in Holland and of Waaler in Norway on the familial incidence of cancer. I have reviewed the evidence in some detail in two recent papers and I need only summarize it here. There are certain organs—the mamma, the uterus and the prostate—in which there is a very high familial incidence which is restricted to one particular organ. The immediate female relatives of a woman with breast cancer show a remarkably high incidence of breast cancer but not of cancer in other organs nor do their male relatives show an abnormally high familial incidence. Similarly the female relatives of a woman with uterine cancer show a high incidence of uterine cancer. In such tissues as the skin or the lip there is no very clear evidence of a high familial incidence while some organs such as the stomach show a definite increase though it is much less marked than for the mamma, uterus and prostate. The extraordinary degree to which the incidence of mammary cancer is influenced by the family history is well illustrated in the accompanying diagram which represents the proportion of cancer of the mamma in the total incidence of cancer in two populations—one the general female population and the other the population of female relatives of patients with mammary cancer.

Diagram showing the comparative total cancer incidence in men and women and the share of breast cancer in the total cancer incidence in (A) the general population (Holland) and (B) the relatives of patients with breast cancer.

It is necessary to mention that even for those organs where the familial incidence is high only a proportion of the relatives—about 25 to 30 per cent.—develop cancer. Even so these findings have a very important practical bearing on the early diagnosis of cancer particularly in such organs as the mamma, uterus and prostate. Thus the existence of a history of mammary cancer in the relatives of a middle aged patient who presents herself with symptoms suggesting the possibility of a malignant growth in the mamma would in my opinion justify an immediate operation even if the diagnosis of a malignant growth has not been established beyond a doubt.

#### A Preventable Disease

The search for the stimuli and agents responsible for the incidence of cancer in man is a most difficult task. We know that stimuli and agents carcinogenic for one tissue are not necessarily carcinogenic for other organs and that even if we restrict ourselves to one organ the agents capable of eliciting cancer in that organ are numerous and diverse. Perhaps the greatest difficulty in this search is due to the conditioning influence of suscepti-

bility. As a result of this when two individuals are exposed to the same carcinogenic stimulus one may develop cancer while the other remains free from it. In spite of these difficulties we are now beginning to acquire a knowledge of the *origin of cancer* in man which will make cancer a *preventable disease*.

The recognition of cancer in man as essentially a preventable disease is in my opinion one of the most important results of scientific cancer research. It is based on the correct interpretation of the well-known characteristic age incidence of cancer in the light of the knowledge obtained by the experimental study of carcinogenesis to which I have referred earlier in this lecture—namely that the onset of cancer is not a sudden one but is always preceded by a long period of induction occupying a considerable fraction of the span of life of the species during which the tissue in which the phenomena of malignancy eventually develop undergoes definite pathological changes. I correlated these two phenomena in a B.M.A. lecture in 1925 and a further study of this relationship emphasized its importance for it meant that cancer was in principle a preventable disease. What is necessary now is an application of this knowledge to the study of cancer in man. We can now search for the origin of cancer by identifying the pathological conditions which precede the onset of cancer and their causes.

In certain tissues such as the skin, the tongue and the vulva—that is to say tissues which are readily accessible to inspection—the existence of precancerous conditions has long been recognized by clinicians although the validity of such a conception was questioned by many pathologists. In any case it was not recognized that these conditions represent special examples of a general phenomenon which is applicable to the vast bulk of the cases of cancer occurring in all organs. It is only in quite recent years when our knowledge of the origin of cancer has made rapid advances that an attempt has been made to correlate the incidence of cancer in organs not accessible to inspection with preceding disorders and diseases.

#### Clinical Correlations

A very striking example of such a relationship has been demonstrated recently. At the International Cancer Congress in Brussels in 1936 two physicians (Dr Ahlborn from the Cancer Centre in Stockholm and Dr Wasink from the Cancer Centre in Amsterdam) read two papers with the identical conclusion—namely that cancer of the mouth, pharynx and oesophagus in women is preceded with surprising frequency by a type of anaemia known as simple achlorhydric anaemia, which is associated sometimes with dysphagia and is then known as the Plummer-Vinson syndrome. This type of anaemia occurs usually in women from an early age to middle age onward. It is characterized by achlorhydria and an early loss of teeth. The nails are frequently soft and spoon shaped. In this condition the mucous membrane of the mouth, tongue and hypopharynx is pale, dry and atrophic and there are often fissures around the mouth. The facial type is said to be readily recognizable.

In Ahlborn's figures of 133 women with cancer of the buccal cavity and oesophagus ninety-nine (61 per cent.) had suffered from simple achlorhydric anaemia with or without dysphagia. Here there is a disease recognized as a separate entity more than twenty-five years ago and readily recognizable which after many years is followed very frequently by the development of cancer in certain definite sites. There is at first sight no obvious connection between the two diseases. This and the failure to recog-

nize that the origin of cancer has to be sought for almost always in some pathological condition pre-existing for many years are the reasons why the association between the two diseases has not been recognized until recently. This type of anaemia is readily curable by iron and hydrochloric acid, and since such treatment restores also the atrophic condition of the epithelium to the normal it is practically certain that the effective treatment of this type of anaemia will prevent the subsequent development of cancer which would otherwise occur in certain sites in two-thirds of the patients suffering from this type of anaemia. Although this relationship affects a number of women which is numerically small it is of fundamental importance, for it demonstrates clearly the possibility of elucidating by clinical investigations the origin of one particular form of cancer, from which its prevention logically follows.

I am convinced that a similar aetiological relationship can be found for the occurrence of cancer in many other organs. Thus Hurst has presented evidence that carcinoma of the stomach is frequently preceded by organic and functional changes—namely, a gastritis associated with either a hypochlorhydria or a hyperchlorhydria. Here, however, the relation between these disorders and the subsequent development of cancer is not so simple as in the example which I have just given. These preliminary disorders may, according to Hurst, give rise to a variety of gastric diseases. They tend to malignant disease of the stomach only in those constitutionally disposed to gastric cancer. The causes of gastritis are widespread and trivial, and consist largely of mechanical, thermal, or chemical insults to the gastric mucous membrane, resulting from such conditions as imperfect mastication, septic infections in the buccal cavity, dietetic irregularities—in a word, from imperfect alimentary hygiene. They can therefore be avoided.

Statistical investigations have given valuable information pointing to the same conclusion. The late Dr Stevenson showed, fifteen years ago, that when the male population of England is divided into five social classes the incidence of cancer of all sites exposed to injury increases rapidly as we descend the social scale, but is approximately equal for the sites not exposed to injury. The exposed sites consist of the skin and the upper alimentary canal, including the stomach. By making a similar analysis for a Continental country (Bavaria) where suitable statistical material is available I could confirm Stevenson's observation. The incidence of gastric cancer shows, then, that the external agencies responsible for the development of cancer in the stomach can be avoided, and are avoided more successfully by the upper social classes than by the lower ones. Here, again, there is evidence that cancer of the stomach is to a large extent preventable.

I have already referred to the recent findings of Horning and myself that cancer of the mamma in a certain strain of mice is due to an endocrine imbalance between the ovarian hormone oestrin and an anterior pituitary hormone which is the physiological antagonist of oestrone. The imbalance can be restored experimentally by the injection of an anterior pituitary hormone—and mammary cancer can thus be prevented. We must, therefore, search for endocrine factors in the aetiology of mammary cancer in women. Here, again, one must not assume that all cases of mammary cancer have the same aetiology. The endocrine type is most likely to be found among women with a marked familial incidence of mammary cancer. Perhaps the statistically established fact that breast cancer is more frequent in unmarried women than in married

women—and that, moreover, in women equally exposed to the risk of pregnancy it is more frequent in those women who are less fertile—may find an explanation in such an endocrine imbalance.

### Need for a "Follow-down" System

The task of establishing in man such aetiological relationships is not an easy one. It is rendered more difficult by the lack of a suitable organization. We have to-day in many hospitals a "follow-up" system for cancer patients. This has as its object to trace the results of treatment. What we need now is a 'follow down' system for cancer patients in which the development of the disease is traced down to its origin. Such a system requires the careful clinical examination by a trained physician of a large number of cancer cases with special regard to their previous history. The relation between a certain type of anaemia and the subsequent development of cancer in certain sites was established by two clinicians working in two cancer centres. It would seem necessary, therefore, to establish in a few hospitals a separate department, under the control of a physician, through which all patients admitted to the hospital suffering from cancer of the internal organs, especially those which are numerically important, such as the breast, uterus, and digestive tract, must pass for an investigation into their previous medical histories.

But perhaps the greatest difficulty is the unjustifiable pessimism which pervades the medical profession concerning cancer. We are still being told by distinguished clinicians that cancer is a mystery, that we know nothing about cancer, and that we must wait until the cause of cancer is found—whatever that may mean—when the cure for cancer will automatically follow, which is by no means true.

Cancer is, unfortunately, a sensational disease, but the prevention of cancer is unsensational work. The physicians who prevent a hundred cases of cancer have less evidence to establish their success than the surgeons or radiologists who cure five, nor will they get for their achievement any credit or financial reward. The results of prophylactic work will become evident only after many years by a careful analysis of the national mortality statistics.

We often hear of proposals for an educational propaganda among the public for an earlier diagnosis of cancer, what is much more needed is an educational propaganda among the medical profession to establish in their minds the conviction that cancer is largely preventable and that every effort should be made to prevent it.

## THE ALLEGED EFFECT OF ACETYLCHOLINE ON IMMOBILIZED JOINTS

By

A. M. HARVEY, M.D. Baltimore

(From the National Institute for Medical Research  
Hampstead London)

Neuburger and Scholl (1937a) have recently claimed that acetylcholine given by subcutaneous injection relieves or prevents the ankylosis and muscular atrophy which normally follow the immobilization of the limbs of experimental animals. In their experiments the knee joint and ankle joint of one hind limb in each of twenty rabbits were immobilized by means of a plaster bandage several layers thick which extended from the great trochanter of the femur to the toes. The ten animals which served as controls showed ankylosis and a high grade of muscular atrophy after three to four weeks of continuous immobilization. The remaining ten animals received 10 mg of acetylcholine subcutaneously every second day until a course of eleven to fourteen injections had been made when the plaster was removed. All the joints were found to be entirely free to passive movement in active motion there was a slight sparing of the previously immobilized extremity, but this disappeared after a few hours. The muscles of the leg seemed fully normal and did not differ from those of the other hind limb.

In a more recent report Neuburger and Scholl (1937b) have extended their observations. A group of twelve rabbits were treated in the same manner but the dose for injection ranged from 0.1 to 10 mg. It was found that the dose of 10 mg gave the best results, and no effect was observed with doses below 3 mg. Six more controls were studied with this group and all showed ankylosis when the casts were removed. Atropine did not counteract the beneficial effect. When prostigmin and atropine were given before each injection of the acetylcholine a dose of 3 mg was found to be sufficient to prevent the ankylosis and atrophy. The authors state that because of the similar action of acetylcholine and histamine on the blood vessels of the rabbit the latter drug was given to a series of eight animals prepared in the same fashion. 15 mg of histamine hydrochloride was administered subcutaneously every two days to a total of fourteen injections. A beneficial action was reported but it was not so good as that obtained with the acetylcholine. In view of the practical importance of this suggested new action of acetylcholine it was thought advisable to repeat these experiments following as closely as possible the technique for immobilizing the limb described by Neuburger and Scholl.

Twelve rabbits of different sexes each weighing between 2 and 3 kg were used. As in Neuburger and Scholl's experiments the right hind limb was firmly wrapped in a bandage impregnated with plaster six yards in length and one inch wide extending from the greater trochanter of the femur to the toes. The animals quickly became accustomed to the cast and by using it as a crutch were able to get about quite easily. They were allowed to run about freely in a small room.

Of these rabbits seven were used as controls. Two received a subcutaneous injection of 1 c.c. of 0.9 per cent saline each second day and the other five the same quantity of a dummy solution containing the same

amounts of choline and sodium acetate as would be liberated by the hydrolytic decomposition of 10 mg of acetylcholine. The five remaining rabbits were given 10 mg of acetylcholine in 1 c.c. of saline solution each second day. The injections were made beneath the skin covering the shoulder blades. Some respiratory distress and collapse was observed to follow the acetylcholine injections but the animals recovered rapidly and in their general behaviour closely resembled the controls. All of the animals received from twelve to fourteen injections over a period of about four weeks at the end of which time the casts were removed.

After the casts had been in position for some time they showed in practically all cases a tendency to become a little loose. The muscular atrophy resulting from the immobilization which is one of the effects described by Neuburger and Scholl in their controls makes it inevitable that the fixation should thus become less perfect with the progress of the experiment. This loss of complete immobility in the later stages must be encountered if the cast is initially applied as closely as is possible without impairment of the circulation in the leg and foot. In my series it affected equally the rabbits treated with acetylcholine and the controls. When the animals were finally anaesthetized with ether and examined more thoroughly before being killed under the anaesthetic for further study the opportunity was taken to examine the circulation in the neighbourhood of the joints by incising the tissues. In all cases free bleeding followed the incisions showing that the circulation had been well maintained.

The results of the plaster fixation were the same in all the rabbits whether treated with acetylcholine or with either of the control solutions. All showed changes of the kind observed by Neuburger and Scholl in their control rabbits and none revealed any trace of the amelioration or prevention of these effects which they attributed to treatment with acetylcholine. In every case there was limitation of movement both at the knee joint and the ankle joint and this limitation persisted under deep anaesthesia with ether. When under the terminal anaesthesia strong force was applied to produce flexion of the joints crepitations were felt and a snap as of adhesions being broken was often audible. In spite of this not quite perfect immobilization or some of the limbs the muscles in every case showed a pronounced atrophy of disuse being very much smaller than the corresponding muscles in the other normal leg. All these effects were present and without perceptible difference in degree in the rabbits treated with acetylcholine as in the two groups of controls.

I am unable to suggest any explanation of the contrast between my negative results and those reported by Neuburger and Scholl in which they describe a prevention by acetylcholine of the effects of immobilization so certain that they are able to study it quantitatively with gross dosage. I have thought it desirable to record my completely negative experience since Neuburger and Scholl's publications may well lead to an application of this method in surgical practice. My own experiments suggest no likelihood of its success.

### Summary

Neuburger and Scholl have recently reported that acetylcholine prevented the ankylosis and muscular atrophy normally resulting from the immobilization of the hind limb joints of rabbits.

Their experiments have been repeated, but no differences between the control and treated animals, as described by these authors, could be demonstrated

This work was done during the tenure of a Medical Research Fellowship of the American College of Physicians

I wish to express my thanks to the Medical Research Council for allowing me the privilege of carrying out these experiments in the laboratory of Sir Henry Dale

## GLASGOW EXPERIENCE OF INCREASED DYSENTERY PREVALENCE

BY

E. BLOCH, M A, M B, Ch.B, D P H.

*Public Health Department Glasgow*

During the past three years the annual number of dysentery cases registered in Glasgow has been increasing and has become relatively high. During the second half of 1937, too, the city, with 203 cases, shared in the reported country-wide increase in prevalence. I attempt here a brief review of some aspects of the prevalence of dysentery during these years and on previous occasions of raised incidence.

### Annual Incidence

Dysentery became notifiable in 1919, when 117 cases were registered. During the nine years thereafter the annual number of notifications was small, often being less than twenty. In more recent years the number has been increasing, and has exceeded a hundred again on five occasions—namely, 1929, 119, 1932, 136, 1935, 135, 1936, 239, 1937, 272. The annual average over the whole period 1919-37 was 81.4.

## OTHER DIARRHOEAL DISEASES

There has not been any apparent regular association between increased prevalence of dysentery and that of other diarrhoeal diseases. It is true that in 1919 and 1932 an increased number of deaths from diarrhoea were registered, that in 1935 enteric and paratyphoid fevers were more prevalent than usual, and that 1936 was a high year both for paratyphoid cases and for deaths from diarrhoea. On the other hand, deaths from diarrhoea were more numerous than usual in 1920, 1921, and 1926, also, the incidence of enteric fever was relatively high in 1920, and that of paratyphoid B fever in 1927, 1930, and 1933.

### Seasonal Incidence

Reports from various sources regarding the seasonal incidence of dysentery differ widely. The years under special review here might be regarded as revealing some resemblance between the seasonal incidence of dysentery and that of the other diarrhoeal diseases. Deaths from diarrhoea and enteritis are highest in either the third or the fourth quarter of the year. Enteric infections are most frequent in the third quarter. Paratyphoid infections are less regular in this respect than typhoid, and, indeed, a large outbreak of paratyphoid B comprising 159 cases in Glasgow and forty-one other cases in neighbour-

ing county areas occurred in the spring of 1936. The total seasonal incidence of dysentery during the past three years was as follows:

	First Quarter	Second Quarter	Third Quarter	Fourth Quarter	Total
Home Infections	41	65	136	106	348
Institutional Infections	116	13	59	110	298
Total	157	78	195	216	646

It is held that the true seasonal tendency of the disease is obscured in the figures with respect to institutional cases by reason of special opportunities for spread, then dysenteric infections would appear to be most frequent in the third quarter, as suggested by the figures regarding cases infected at home. From the following list it will also be noted that of fifteen outbreaks of dysentery the numbers commencing in each quarter of the year were respectively 4, 0, 8, and 3. Of twelve institutional outbreaks included in the list the quarterly distribution of the onset was 4, 0, 5, and 3.

### Outbreaks

The outbreaks recorded up to the end of 1936 and those now falling to be recorded for 1937 were as follows:

Date	Outbreak
1928 Aug Sept	7 fatal institutional cases among infants. 2 positive Sonne. Reported by Hay (1930).
1929 Aug Nov	51 cases and carriers in group of overcrowded tenements. 35 positive Flexner including 9 symptomless persons. No common source detected. 93 other cases of enteritis investigated.
1930	5 of 10 institutional cases positive Sonne.
1933 January	Small Flexner Z institutional outbreak.
Aug Sept	Small Sonne institutional outbreak affecting children.
August	7 children positive Sonne of 12 cases which sickened 1-3 days after consumption of suspected ice-cream.
1934 March April	5 of 13 institutional cases positive Sonne.
1936 January only	60 positive Flexner (X or Z) of 104 cases in large Poor Law institution including 20 positive food workers. Total inmates excluding staff 1343. 23 patients sickened in first 5 days after eating suspected meat pies on January 1, then 29, 27 and 24 in successive weeks. 10 aged patients died.
September	9 positive Sonne cases associated with ice-cream—2 in family of vendor and 7 cases sickening 1 to 2 days after consumption.
Sept Nov	13 positive Sonne and 2 Flexner in children's institution.
1937 Jan March	23 young children and 2 nurses notified from large general hospital. Sonne and Flexner W, X and Z. Again.
Aug Sept	23 young children and 2 adults notified from this institution. Sonne and Flexner W, X and Y. Total cases notified in 1937 from this institution 60, mainly Flexner. Several of the food untraced.
September	9 men notified as cases of Flexner dysentery from ward in large general hospital which later housed the big outbreak described below.
Oct 21 Nov 4	Fever hospital staff outbreak affecting one doctor and 34 nurses with 14 positive Sonne. Cases sickening on successive days—1, 2, 2, 2, 2, 3, 5, 5, 3, 4, 1, 2, 1, 0, 2. Possibly due to fresh fruit eaten October 20. Controlled by removing cases from nurses' home to special ward.
Nov Jan 1938	5 positive Sonne of 11 cases among staff and female patients in large mental institution. First case mixed inmate of old standing. Good isolation accommodation. Notifications in 1938 figures.
Nov Jan 1938	94 cases and 12 carriers in large general institution with 86 positive of whom 78 were positive Sonne. Described below. 42 cases included in 1937 figures. 386 other persons investigated including 114 with close contacts. Total persons examined 492.

### True Incidence of Dysentery

The above list sheds light on some factors in the frequently discussed disparity between the notified cases of dysentery and its true incidence. Of 121 positive findings in two outbreaks twenty one were made regarding persons free from symptoms and of 349 persons comprised in nine outbreaks only 219 yielded positive specimens. It therefore seems probable that despite the increased attention recently paid to dysentery many mild and many bacteriologically negative cases remain unnotified. More over suspicion of dysentery may not be raised when cases do not occur in groups and it is also known that investigation and notification are withheld in some cases that do incur suspicion. Other considerations tend to limit the extent of disparity between true and apparent prevalence. In connexion with two outbreaks regarded as comprising 157 persons 207 contacts with loose motions were investigated with negative result. Also in connexion with one outbreak regarded as comprising 106 persons 386 contacts were examined with negative result.

### Food borne Infection

It will be noted that food has been incriminated or suspected as the vehicle of infection in respect of both types of bacillus and both in institutional and in non institutional environments. Besides the two listed Glasgow outbreaks of Sonne dysentery attributed to ice cream, a small county Flexner outbreak traced to ice cream was investigated in the city laboratory in 1931. In 1926 too a county outbreak of eighty cases of Sonne dysentery associated with a milk supply had been investigated in the city laboratory as reported by Wiseman (1927) in the first record of the appearance of Sonne dysentery in epidemic form in the West of Scotland.

### Institutional Infections

Institutional infections form a substantial and increasing proportion of the total number of cases as will be seen from the following list.

Year	Institutional Infections	Home Infections	Total Cases Registered
1935	4	93	135
1936	111	123	239
1937	145	127	272

It will also be noted that the excess of total cases for 1937 over 1936 is accounted for by institutional cases.

Periods of high institutional incidence are of course not necessarily periods of high domestic incidence because any one institutional focus may become enlarged owing to the special conditions existing in institutions. For example in January 1936 sixty eight cases from institutions were registered but only eight home cases were notified. Sometimes domestic registrations have been high without an associated increase in institutional cases. For instance in the three years 1935-7 the following numbers of home and institutional cases were registered in September the month with the highest total of home cases over that three year period 25 and 528 and 6 and 23 and 16 respectively. In December 1937, however when the prevalence in other parts of the country was also notably high there was a simultaneous notable rise in the number of home infections which totalled twenty eight and of institutional infections which totalled forty four. On the whole some relation does probably exist between the

two classes of cases. The third quarter was the one giving the highest figures for domestic registrations during the past triennium and also for the onset of various outbreaks recorded over several years. It is indeed reasonable to assume that infection will be more often introduced into institutions when its prevalence in the general community increases.

Institutional cases appear to fall into two categories. In one a definite cause can be recognized—for example contamination of food or secondary spread from a previous case. In the other are those institutional patients who become sporadically in the manner of cases ordinarily arising in non institutional communities and more than one type of endemic dysentery organism may thus participate in the prevalence. In respect of the relative frequency of institutional cases in this category dysentery differs from the enteric infections institutional outbreaks of which usually are traceable to a definite source—a difference doubtless due to the greater general severity of enteric infections and to the longer duration of the ensuing carrier state.

### Sex Incidence

The gross figures for all cases of dysentery without subdivision according to type of bacillus revealed no special feature with regard to sex incidence. For the years 1935-7 the sex distribution of the registered cases was as follows.

	Males	Females
Home Infections	137	161
Institutional Infections	140	1
Total	277	162

### Age Incidence

The figures with respect to the age of incidence of both institutional and non institutional cases confirmed the recognized high incidence of dysentery under the age of 15 and especially between the ages of 1 and 14. True dysentery does occur under 1 year of age but with relative infrequency. Although a large proportion of cases of summer diarrhoea in America appear to be due to dysentery Blacklock, Guthrie and Macpherson (1937) working in Glasgow state that in common with other British investigators they have rarely isolated dysenteric bacilli in cases of infantile diarrhoea apart from cases of frank dysenteric ileocolitis. The total figures for the years 1935-7 were as follows.

Age	-1	-5	-15	15-25	25-35	35-45	45-55	55-65	65-75	Total
Home Infections	6	35	5	13	1	1	1	1	1	75
Institutional Infections	17	9	15	1	1	1	1	1	1	57
Total	23	44	20	14	2	2	2	2	2	132

Thus 306 cases occurred below the age of 15 and 40 cases above home cases under 15 and of age 15 and over outnumbered those aged over 15.

### Fatality

Deaths certified as due to dysentery remained low. The age distribution of the sixteen persons who died in 1936 and of the nine who died in 1937 of dysentery was as follows.

Age	-1	-5	-15	15-25	25-35	35-45	45-55	55-65	65-75	Total
Cases	1	1	5	15	12	1	1	1	1	41
Deaths	3	1	1	2	1	1	1	1	1	13

The disease therefore appears to be more serious among infants and among the elderly. The number of deaths during 1935 was five. Thus, during the three years of increased prevalence there were thirty deaths among 646 cases. During the years 1927-34 there had been thirty-two deaths among 619 registered cases; the case mortality rate has therefore not risen with the incidence. Dysentery, of course, also plays a part in deaths not included in such figures—that is, when it forms a terminal event in cases where death is certified as primarily due to pre-existing illness.

### Organisms

A majority of the cases of bacillary dysentery are probably still due to the Flexner type of organism. The presence of Sonne dysentery in Glasgow was first recorded in 1928, when the outbreak reported by Hay and a few other isolated cases occurred. During the years 1929-36 positive specimens from Glasgow, according to the city bacteriologist, have numbered 413 Flexner and 278 Sonne. Positive Sonne specimens have exceeded positive Flexner specimens in the central city laboratory only in 1930, 1933, and 1936, and in 1936 a large institutional outbreak with sixty positive Flexner cases was investigated in a hospital laboratory. It is also of interest to note that, in 1936, of fifty positive specimens submitted from a town near Glasgow thirty were Sonne and twenty Flexner. Carter (1937) reported the results of his examination of eighty-eight Flexner strains isolated from Glasgow cases during 1936 and 1937. The staff of Dr F. E. Reynolds, Stobhill Hospital, also recently examined ninety-five Flexner strains derived from the hospital. The results were as follows:

	V	W	X	Y	Z	WX	XYZ	Total
Carter	—	16	8	3	60	1	—	88
Reynolds	—	28	23	29	14	—	1	95

Although one type of organism usually predominates in any group, it is not uncommon to find different types and strains of these endemic dysentery organisms associated in a multiple focus. Examples of this association are included in the list of outbreaks given above. In 1934, too, four persons in a family were found positive for Flexner and two others positive for Sonne. In the autumn of 1932 four positive findings of paratyphoid B and three of Sonne dysentery had been made regarding seven persons living in an insanitary tenement. Also, in the large Sonne epidemic described below, a man unusually ill with positive Sonne dysentery was found to be a chronic urinary carrier of *B. typhosus*.

### A Large Outbreak of Sonne Dysentery

The first large Glasgow outbreak of Sonne dysentery occurred in a big general municipal institution towards the end of November, 1937, and continued till the end of January, 1938. It therefore appeared at a time of exceptionally high country-wide prevalence of dysentery. In December forty-two cases were registered from this focus and only two from other Glasgow institutions. Home infections numbering twenty-eight were also registered in Glasgow in December. The seventy-two December cases thus constituted over a quarter of the year's 272 cases. Although the possible sources of introduction of dysentery into the institution were therefore more numerous than usual, it is to be remarked that of the ten Glasgow home infections registered in November and of the twenty-eight registered in December only one and four respec-

tively occurred in the city division containing the institution. Moreover, apart from a few households whence patients were admitted suffering from frank dysentery, no infections were reported from the homes of infected patients, a large proportion of whose visitors would be derived from these homes. Also, no dysentery cases were registered from the homes of the infected staff members.

The epidemic assumed the form of two successive waves of infection. The following number of acute cases, all positive for Sonne except one positive for unspecified dysentery, sickened in successive weeks from November 20, 1937, 2, 20, 5, 4, 0, 9, 1938, 15, 6, 1, 1, 2, 0, making a total of 65 positive acute cases of Sonne and unspecified dysentery. Other positive findings were:

Cases admitted with dysentery: Sonne 6, Flexner 1.  
Acute institutional infections: Flexner 1, Flexner W 1.  
Symptomless temporary carriers: Sonne 8, Flexner 1, Flexner X?, unspecified 1.  
Total positive findings: 86, including 78 Sonne.

Acute cases numbered sixty-seven as detailed. Only twenty other persons were regarded as clinical cases yet gave negative specimens. These were not notified, but they would raise the total of infected persons to 106. The detection of so large a proportion of positive cases was doubtless due to the facilities for relatively prompt bacteriological examination. Negative specimens were also obtained from 114 persons with loose motions or incontinence and from 272 persons free from suspicious symptoms. Six of the positive cases ended fatally during December and January. These persons were all elderly, and suffered, moreover, from pre-existing illnesses.

The patient admitted with Flexner dysentery and two patients admitted with Sonne dysentery produced no secondary cases. Of the six patients admitted to the hospital wards suffering from Sonne dysentery four were associated with only six other cases that could be regarded as possibly attributable to the admissions, even when among the secondary cases is included one sickening two and a half hours after the admission of a dysenteric patient to an adjacent bed in an otherwise uninfected ward. In one of these groups the interval between the removal of one secondary case and the sickening of another was eight days.

Since many of the cases were clinically extremely mild it is not surprising that eight persons were classified as symptomless Sonne carriers. None of the carriers could reasonably be regarded as chronic, and indeed it is generally accepted that symptomless chronic carriers of bacillary dysentery are rare. Five of nine staff members found positive were symptomless. Neither the carriers detected among the staff nor those detected among the patients were so situated as to account for all the other wise untraced foci of infection in the outbreak. The acute infections among the staff occurred after the outbreak had begun.

There was no definite evidence of spread of infection by food, milk, or water, but it was thought important that the milk supplies should be scalded in the wards and attention devoted to the methods of cleansing food utensils, especially milk containers, passing through the central kitchen and dairy premises. It will be noted that no incidence of Sonne dysentery was detected in these departments, all the members of the staff of which were examined bacteriologically.

The most noteworthy feature of this outbreak was the apparently sporadic way in which some of the affected individuals sickened within the institutional community. The first cases in the institution were female inmates of old standing in the chronic sick block. The disease sub-

sequently appeared in other non admitting blocks of the institution. Similarly acute infection reappeared in wards which had been free from dysentery cases for two to four weeks and in which the presence of carriers had not meanwhile been demonstrable. The following list gives some details of incidence in all sections of the institution.

#### Female chronic sick wards

9 of 17 wards affected between November 20 and January 27  
Inmates 192 Positive findings 41 including 1 nurse

#### Male chronic sick wards

6 of 18 wards affected between December 3 and January 29  
Inmates 18 Positive findings 13 including 1 nurse and 1 maid

#### Male mental observation wards

90 inmates 3 positive acute cases on December 3

#### Male mental wards

159 inmates 4 positive acute cases January 6-11

#### Female mental wards

222 inmates 3 positive acute cases January 3 and 31

#### Female mental observation ward

27 inmates No cases

#### Hospital wards

8 of 19 wards affected from December 12 to January 16. Total inmates 525. Positive findings 17 including 1 doctor 7 admissions and 6 possibly secondary cases

#### Staff

Total 64\* of whom 233 lived in and 410 lived out. 5 positive findings—namely 3 nurses (not employed in any infected ward) a kitchenmaid (Flexner carrier) and a food porter to chronic sick block (Flexner carrier). 2 nurses 1 maid and 1 doctor are mentioned above. Of the 3 nurses infected 3 were symptomless Sonne carriers so that 5 of the 9 staff members found positive were symptomless.

Total population of institution	1629	20.9
Non resident staff	410	
Persons examined bacteriologically including those found positive	492	
Positive findings	36	

### Summary

Dysentery registrations in Glasgow between 1919 and 1934 averaged 56.3 annually. Between 1935 and 1937 the annual total of institutional infections rose from 42 to 145 and the annual total of cases averaged 215.3. Some epidemiological aspects of these 646 registrations have been noted. Previous occasions of increased prevalence and sixteen outbreaks including thirteen in institutions recorded since the introduction of compulsory notification in 1919 have been adduced. Glasgow with 203 cases including seventy-two in December shared in the widespread increased prevalence during the second half of 1937 and towards the end of that period experienced the onset of its first large outbreak of Sonne dysentery. Some details have been given of the incidence of the eighty six positive findings (seventy-eight Sonne including eight not associated with symptoms) made during this institutional outbreak. In the absence of case to case connexion between several foci within the outbreak it was considered important to devote attention to the methods of cleansing the ward food utensils handled by the uninfected staff of the central kitchen and dairy.

I am indebted to Dr A. S. M. Macgregor for the suggestion to compile these notes, also for criticism and permission to publish.

## CARCINOMA OF THE PALATE HOW OFTEN DOES IT MASK MALIGNANT DISEASE IN THE MAXILLARY ANTRUM?

BY

JOHN R. NUTTALL, M.D., D.M.R.

National Radium Officer, Marchister Centre, Assistant  
Medical Officer, Christie Hospital and Holt Radium  
Institute

In the 1936-7 Statistical Report of the National Radium Commission the relatively low proportion of patients with carcinoma of the palate who have remained free from recurrence after treatment is commented upon. The report states that the low proportion of patients with carcinoma of the palate who have remained free from recurrence is unexpected in view of the fact that the survival rate for this group approximates closely to that for the alveolus and that this group shows the highest proportion of patients free from glandular metastases when treatment was started. The figures given suggest that there is a tendency for tumours of the palate to spread further than can be easily recognized by clinical means with the result that the tumour is often inadequately irradiated and thus tends to recur with greater frequency than tumours of the other sites. This particular problem was noticed some years ago at the Holt Radium Institute and led to investigation with a view to finding and remedying the cause. Although at the time of the original investigation certain definite information was obtained it was felt that the available cases were too few to justify publication of the inferences from the observation.

At the present time analysis of 167 cases of malignant palatal ulceration and of 104 cases of antral carcinoma passing through a single clinic is possible and in view of the comments in the Radium Commission Report it would appear expedient that the conclusions to be drawn from that analysis should be placed on record. As a result of the investigation I suggest and this article purports to demonstrate that the tendency to recurrence after treatment of carcinoma of the palate is due to the fact that a large proportion of palatal growths are really neoplasms of the antrum. It will be shown that with certain limitations which will be discussed in their appropriate place it is a wise generalization that a case of carcinoma of the palate must be considered and treated as an antral growth unless it has been proved not to be so. This generalization corresponds with those which nearly every medical student finds helpful with regard to malignant disease of the stomach, uterus and rectum.

### Material for Study

The material upon which this analysis is based is a group of 167 cases of palatal neoplasm and 104 cases of malignancy involving the maxillary antrum put together in the 167. Only those cases in which the palate was the site of major involvement have been considered. The patients were referred in part by general practitioners and in part by the surgical consultants on the outpatient staffs of the general hospitals in the area served by the Institute. In fairness it should be stated that failure to recognize the antral involvement of many of the palatal tumours was not restricted to the former of these two groups.

The term malignant disease involving the maxillary antrum has been chosen to avoid any implication that it is considered that all or even the majority of the

tumours reviewed necessarily originated in the antrum. The investigation was undertaken to obtain information for the purpose of improving the results of treatment of malignant palatal ulceration. From a treatment point of view it matters little which side of the palate was first involved if both sides are involved at the time the patient is treated, since both sides have to be dealt with in any case. The majority of palatal growths could be grouped either as "anterior" or "posterior," although every part of the palate was represented in the cases studied. The posterior growths were usually associated with soft-palate ulceration, and frequently with extension on to fauces and tongue. They formed a group which a certain type of radium implantation (referred to in the Institute as a tongue-ptyergoid implantation") was generally successful in curing locally. Glandular involvement was usually the reason for eventual failure to cure, and many of the patients had involved glands when first seen.

The "anterior" group were found to involve the palate, upper alveolus, sulcus between cheek and alveolus, and sometimes the cheek in the neighbourhood of the

Typical antral site

alveolus. The actual site of this lesion was fairly constant, being about the junction of the middle and anterior thirds of the alveolus. Glandular involvement was rare, except as a late event. Local treatment of the obvious lesion was often followed by recurrence involving the maxillary antrum.

The factors which determined a final diagnosis of antral involvement may be summarized as follows. In the majority of cases the diagnosis was made before treatment, by radiographic demonstration of bone destruction. In others the diagnosis was arrived at only after failure of local palate treatment had been followed by recurrence accompanied by bone destruction revealed on x-ray examination or presentation of an obvious tumour eroding through another wall of the antrum.

#### Typical Antral Site

For convenience the anterior situation just described will be referred to as being in the "typical antral site." It may immediately be questioned whether this term can be justified. In Table I 167 cases of malignant ulceration of the palate are analysed with regard to site and antral involvement.

TABLE I—167 Palate Growths Analysed According to Site and Antral Involvement

Total number of cases with ulceration of palate	167
A Ulcer in typical site	96
Typical site ulcers involving antrum	91
B Ulcer not in typical site	71
Non typical ulcers involving antrum	1

The table shows that of ninety-six typical site lesions ninety-one at some period involved the maxillary antrum (94 per cent), whilst of the rest only one in seventy-one (1.4 per cent) did so. There can be no doubt that these figures justify the term.

The textbook description of antral malignancy usually given is of a history of nasal discharge and hemorrhage, often associated with pain in the maxilla, and trismus. There may or may not be nasal polypi. Later, as the tumour increases in size, there is extension beyond the walls of the antrum. A tumour presents most frequently in the malar region, orbit, or nose, but it occasionally occurs in the nasopharynx or the palate. Not infrequently several of these sites are involved. In actual clinical experience, however, it is very often the presence of one of these obvious tumours that is the immediate cause of the patient's decision to take medical advice. The obvious lesion results in a diagnosis of carcinoma of the nose or rodent ulcer of the inner canthus or epithelioma of the palate being made and treatment for this condition being instituted.

In Table II all the cases of maxillary antrum malignancy seen in the clinic are analysed according to the anatomical sites obviously involved.

TABLE II—Site of Obvious Involvement in 104 Antrum Cases

Site	No.	Percentage
Intra oral only	71	68.5
Both intra oral and extra oral	21	20
Mouth therefore involved in	92	89
Extra oral only		
Nose 4 orbit 1 malar 4 more than one site 3	12	11.5
Malar swelling	20	19

The heavy preponderance of visible mouth lesions over extra oral involvement in this group of cases is so obvious as to require no further stressing. Consideration of the incidence of face swelling shows that in only twenty out of the total of 104 cases was this visible. Only two of these are found in the "missed antrum" group.

It may be inferred from these two tables that antral malignancy usually involves a typical part of the palate, and that practically every palatal ulcer in that site involves the antrum. The cases forming the background of this analysis do not bear out the usual view as to the common picture of antral neoplasm. Malar involvement is comparatively rare, whilst the palate is involved in 89 per cent of the cases. It may be argued in reply that because the cases were referred for radiation therapy they were presumably advanced ones, and that consequently the typical picture was distorted. The infrequency of visible involvement of the malar region even in the obviously late cases, however, suggests that this is not the explanation.

#### The Incidence of Missed Antrum

It has been the custom in the Institute to refer to the cases which have been proved to involve the antrum although originally diagnosed as some other condition as "missed antrum." These cases fall naturally into two groups: (1) those which were recognized on first examination in the radium clinic although referred with a different diagnosis, (2) those not recognized until treatment for the first-diagnosed condition had been followed by recurrence. It is necessary in studying these missed antra to consider two proportions. First, there is the proportion of the total antral cases which were missed,

secondly there is the proportion of the total palate cases which were in fact or could have been missed antra

TABLE III—Analysis of Missed Antra in Relation to Total Antral Cases

Total antra analysed	101
Total referred with misdiagnosis	0
(a) Recognized here but missed elsewhere	5
(b) Not recognized at all till recurrence	13

Table III shows that in seven years seventy possible missed antra have passed through a single institution concerned with general malignant disease. This figure represents 67 per cent of the total antral scene. Of these seventy cases fifty five were recognized in the clinic here but fifteen were not.

TABLE IV—Analysis of Missed Antra with Palatal Lesion

Total palate analysed	157
Total involving antrum	92
Total referred with misdiagnosis	64
(a) Recognized here but missed elsewhere	51
(b) Not recognized at all till recurrence	13

The two cases which were not recognized till recurrence took place and which appear in Table III but not in Table IV were diagnosed and treated as rodent ulcer of the inner canthus and as carcinoma of the nose respectively.

When both Tables III and IV are considered it is seen that, while 67 per cent of all the antral cases were misdiagnosed before reference to this clinic 91 per cent (64 out of 70) of the errors occurred in cases with palatal involvement. I submit that this has a very direct bearing upon the comments of the National Radium Commission statistician, to which reference has already been made.

### Clinical Investigation

It follows as an obvious corollary of the foregoing analysis that every case of carcinoma of the palate requires special investigation to eliminate the probability of its really involving the antrum. In this institute the usual procedure is to look upon every palate case with suspicion. If the lesion is entirely in the posterior part of the palate and not lateral no particular investigations are carried out beyond examination of the upper surface of the soft palate either digitally or by inspection through a mirror. A posterior lesion involving the alveolus and the sulcus between cheek and alveolus is investigated as one in the typical antral site. The approach to lesions in the typical site is threefold.

1 *X Ray of Sinuses*—In the advanced case in which there is opacity of the antrum and erosion of the bone between the obvious lesion and the antrum the diagnosis is definite. The presence of an obvious lesion and opacity of the antrum but no bone erosion is suspicious enough to determine treatment. A negative x ray report, however, is not of very great value unless it is confirmed by other examinations. This statement is supported by the fact that thirteen of the fifteen cases of missed antrum which were not recognized until recurrence after treatment were overlooked because negative x ray reports were accepted as conclusive.

2 *The Needle Test*—A sterile hypodermic needle whose sharpened end has been blunted is grasped in forceps and pushed into the tumour. If it passes through the bone erosion is assumed to have taken place. In every case in which the antrum is found to be involved irradiation of the antrum as well as the palate is undertaken. The needle test is useful but is open to criticism and unless the palate is completely perforated it is apt to be

painful. Injection of a local anaesthetic has not proved very helpful on the few occasions on which I have used it. In cases in which only the oral surface of the palate is eroded it is often possible to force the needles through the remaining bone. Probably however in designing treatment lesions of this kind should be considered as already involving the antrum. When the erosion spreads outward obliterating the alveolo-cheek sulcus care is necessary to ensure that the needle is not merely passing upwards in soft tissues completely external to the antrum. Other than in this case a positive needle test ought to be considered to indicate the need for treatment designed to include at least the floor of the antrum in addition to the oral malignancy. Failure to get the needle through the bone has little diagnostic value since the clinician has no sure means of knowing that he has not missed probing the one site which is perforated.

3 *Exploration of the Antrum*—It occasionally happens that both these tests are inconclusive. In these cases either of two courses is open to the investigator: he may decide there and then that the statistical probability of antral involvement is so high that he is justified in carrying out treatment which includes the antrum or he may ask an aural surgeon to open the antrum so that direct inspection of the lining settles the point at issue. Either of these procedures is infinitely preferable to failure to treat an involved antrum for in thirteen of the fifteen missed antrum cases only recognized after recurrence the patients are dead: nine of them in less than a year after recognition.

It may be asked why biopsy has not been included in the description of clinical investigation. For biopsy to be of value antral lesions would need to present an entirely different histological appearance from palate ones and an overwhelming majority of cases. If the did so lesions originating in the antrum could immediately be segregated leaving only the palate lesion perforating into the antrum to be recognized. In Table V the pathological findings in seventy-eight palate cases which did not involve the antrum are compared with those in seventy-five cases of known antral malignancy.

TABLE V—Proportion of Squamous Carcinoma in the Palate and Antrum Tumours

	Number Secured	Squamous Carcinoma	Other Tumours
Palate malignancy not involving antrum	73	5	3
Malignancy of antrum	75	3	16

The table shows that of the seven-eighths non-antral palate growths 96 per cent were squamous carcinomata while of those involving the antrum 79 per cent were of the same histology. Although there is a considerable difference in these percentages the great preponderance of squamous carcinoma in both groups renders any logical examination of little value as a differential diagnostic agent.

### Improvement following Recognition of the Palate-Antrum Relationship

The relationship between lesions of the palate and the maxillary antrum was recognized in this institution 10 years ago after a preliminary examination of the available statistical material. At the time it was difficult to carry out a large prospective study of the problem. The information gained was however used in determining policy with regard to palate lesions.

Having demonstrated a connection and subsequently carried out a prospective study the results showed that

improvement has been effected? I believe that it can. There has been no change in the methods of reference of patients to the Institute over the whole seven years under review, and cases referred as carcinoma of the antrum remain few. The average number of missed antrum cases per year is ten. During these seven years the Institute staff failed to recognize fifteen out of the seventy cases until recurrence took place. Of these fifteen only three have occurred during the last two years—that is, since the high incidence of antral involvement in palate malignancy was realized. Each of these three cases was missed because again a negative x-ray report was accepted as being conclusive.

### Conclusions

It may be inferred from the report of the National Radium Commission that the frequent involvement of the maxillary antrum in certain palatal and upper alveolar malignant lesions is not generally appreciated.

Investigation in the Manchester Radium Institute of 167 cases of malignant disease of the palate showed that 94 per cent of the lesions of the middle third of the palate, spreading on to the alveolus and into the alveolo-labial sulcus, involved the maxillary antrum. In the Institute this is known as the typical antral site. Lesions in the other usual palate site—that is, the posterior part of the hard palate, spreading on to the soft palate and fauces—did so in only 14 per cent of the cases.

Typical antral-site lesions should be regarded as involving the antrum unless it is proved that they do not. If definite proof is not forthcoming they should be assumed to do so, and be treated accordingly. X-ray examination alone is conclusive only when positive. A negative report should not be accepted as being conclusive. Thirteen cases out of fifteen with antral involvement, missed until recurrence followed treatment, escaped notice through the acceptance of negative x-ray reports.

The needle test described is useful, but should only be accepted when positive.

Histological examination does not help to clear up the diagnosis, because of the high proportion of squamous carcinomata in both the simple palate lesions and those involving the antrum, taken in conjunction with the fact that all malignant tumours of the palate are not epitheliomata. As treatment must include both mouth and antrum, anatomical differentiation of site of origin is not considered to be of great clinical importance.

The cases seen in the Institute suggest that intra-oral ulceration is by far the commonest evidence of antral neoplasm. This finding is contrary to accepted teaching, but is not due to the fact that usually it is the more advanced cases which are referred for radiation therapy, as cheek-bulging is rare even in the obviously late cases.

It is shown that recognition of the palate-antrum relationship has been followed by a great reduction in the number of cases entirely missed until local palate treatment was followed by recurrence.

From April 1 the importation into this country of all meat, including bacon and ham and also meat products such as canned meats, sausages, and sausage casings, will be permitted only if they are accompanied by an official certificate recognized by the Minister of Health as evidence of satisfactory inspection and hygienic preparation. The importation of certain defined classes of meat (such as scrap meat) continues to be prohibited.

## TINEA OF THE FOOT

BY

P. K. FRASER, M.B., Ch.B.

Surgeon Lieutenant, R.N.

Since the discovery of pedal tinea by Whitfield in 1908 the condition has become increasingly prevalent (C. J. White, 1927a), and according to American authorities presents to-day one of the major problems of dermatological practice. The many statistical surveys that have been made in America by Hulsey and Jordan (1925), Legge, Bonar, and Templeton (1929), Andrews and Birman (1931), and Gilman (1935), to mention only a few, appear to confirm this, and it seems strange that no comparable figures have been produced in this country. It may be as Gray (1934) said, that "the profession as a whole is still barely aware that the problem exists," and should the disease achieve the lay popularity it has achieved elsewhere there is every danger of a too free diagnosis on inadequate evidence.

### Difficulties in Diagnosis

The frequent and early spontaneous disappearance of fungal mycelia from the infected area is one of the main difficulties, and in late cases there may be nothing to distinguish the condition from dermatitis from other causes (Whitfield, 1908, 1911). The reason for this disappearance is hard to understand in view of the viability of the pathogenic fungi (Farley, 1921; Weidman, 1927a; Bruhns, Alexander, and Kadisch, 1929), but the secondary bacterial contamination which sometimes occurs may in some way exert a lethal influence on the moulds. In this connection the observations of Weidman (1926) on a case of pedal ringworm sown with yeasts are of importance. Thus it would appear that many cases of tinea, when seen, will not show the causal agent, although such authorities as J. H. Mitchell (1922) and C. J. White (1919, 1927b) countenance a diagnosis on clinical grounds alone in the chronic keratotic pedal type. This may be admissible under certain circumstances, but the demonstration of the specific factor still remains a *sine qua non* in diagnosis, and the following statement by Ramsbottom (1931) may be taken as an expression of general opinion.

"There is, however, a tendency on the part of some investigators to assume a fungal origin of a disease on insufficient evidence. It is not enough to postulate the parasitic nature of a disease and then, bacteria, protozoa, and other parasites being eliminated to describe it as mycotic, the evidence must be as clear as that for any other parasitic group."

In addition it must be remembered that all cases of interdigital scaling and maceration are not mycotic, although von Graffenried (1918) and Catanei (1932) have shown that such lesions form a suitable nidus. Dirt seems to bear no relation to infection, as the highest incidence is to be found among the wealthy and more leisured classes (Beintema, 1931). Therefore the practitioner will often be confronted with strong clinical evidence of fungous infection without microscopical or cultural confirmation, and a specific dermal test would be of great help in accurate diagnosis.

### Previous Investigations with Mycotic Extracts

The use of mycotic extracts in the diagnosis of superficial tinea infers an altered state of reactivity in the body. That this state exists in certain bacterial diseases is a well established fact, and for many years mycologists have endeavoured to find a corollary in ringworm infection.

The position with regard to deep ringworm has practically been cleared but the occurrence of general changes in the superficial type has caused much controversy. The tendency towards spontaneous cure in deep tinea (Sabouraud Greenbaum 1924) has been explained by the development of a general immunity and the rarity of scalp infection in adults has been cited as an example of acquired herd immunity. Supporting the development of immunity Greenbaum (1924) and Scholz (1934) showed that by inoculating guinea pigs cutaneously with ringworm they rendered the animals immune to further inoculation and Sabouraud found that he could not use the same animal twice in testing for the pathogenicity of moulds. Greenbaum also showed that by inoculating the skin of a human with *Trichophyton cyaneum* spontaneous healing occurred in four weeks and that the site of the lesion could not be reinfected as long as three months afterwards. Further he claimed that the immunity thus produced was group-specific against the other ringworms and said that so sharply defined is this local immunity that reinoculation of a previously healed site only shows a take at the exact edge of the previous lesion. Disproving this cutaneous immunization as applied to superficial infection Weidman (1927b) was able to infect the first interdigital cleft of his foot on two occasions with *Trichophyton cruris* after a lapse of two years although the interval appears to have been unduly long. It is also not uncommon in tropical practice to see more than one attack of tinea cruris in the same patient despite the fact that Gray (1934) thinks this is rather unusual.

The occasional development of distal phlyctid eruptions in superficial infections has been established by Jadassohn and Peck (1929) Sulzberger and Kerr (1930) Peck (1930) and Ayres and Anderson (1934) while a fungus has been recovered from the circulating blood in some cases (Sulzberger 1928 Peck 1930 Strickler *et al* 1932). It is of interest to note the inhibitory effect on ringworm cultures of serum from cases with phlyctid eruptions (Per and Braude 1928 Ayres and Anderson 1934) Ravaut and Rabreau (1932) even claim general changes in superficial yeast infections and they have used an extract of yeast cultures (levurin) as a diagnostic test.

From the foregoing evidence it is logical to conclude that superficial ringworm can sometimes cause local immunity and there is reason to believe that the products of the causal fungus are not limited to the site of infection.

The diagnostic skin tests have given very variable results in the hands of different investigators. Such an eminent mycologist as Castellani (1934) places little reliance on them although he publishes full details for the preparation of the extract while Tarantelli (1926) and Garzella (1926) insist that to produce a positive result the lesion should be deep seated. Amberg (1910) using linear scarification had thirteen positives from 131 casual patients four of the thirteen had no previous history of ringworm. Repeating this investigation Rosen Peck and Sobel (1931) intradermally tested 102 dermatological patients—seventy-two of them with some pedal skin lesion—and found a positive reaction in sixty seven. There were nine proved cases of tinea pedis in this series and eight of them reacted strongly. Muskatblat and Director (1933) encouragingly report 72 per cent. positive results in 300 cases of superficial tinea while Ruete and Scholz (1934) claim 100 per cent success in proved cases. In addition the last named observers contend that the extract used will only react against the fungus from which it is prepared although this is disproved by Sulzberger and Kerr

(1930). These group reactions are accepted generally and are to be expected in view of the close biological relationship of the pathogenic moulds. Lomholt (1934) and Muende (1934) regard dermal tests as being of especial value in the differentiation of mycotic from dandruff eczema—a matter of importance in this country on account of the insignificance of the mycotic factor in the latter type of lesion (McLachlan and Brown 1934).

### The Present Investigation

The following investigation was carried out in ships or war during the last three summers. In all, 111 cases were examined twenty two of them with superficial pedal tinea the remaining eighty nine were casual patients used as controls. In every case a careful examination of the interdigital crural and axillary folds was made and any skin surface showing maceration or desquamation was examined microscopically for fungus while the previous dermatological history was assessed as to the possibility of a fungus infection. Polyvalent trichophytin (Hoescht) was used throughout in a dilution of 1 in 30 and the diluent was employed as a control. Dilutions of 1 in 2.0 and 1 in 800 were also used at the beginning of the investigation but were soon dispensed with as unnecessary. The solutions were renewed at monthly intervals to ensure against deterioration. After a trial of the linear scar and patch methods the intradermal route was chosen as being the most reliable. The trichophytin was injected with a fine needle into the flexor surface of the right arm and the control was injected in a similar site in the other arm care being taken that the syringes and needles used were dry and free from traces of chemicals.

Four types of reaction were met with (1) immediate and transient urticarial reaction (2) inflammatory reaction (3) inflammatory reaction with vesicle formation (4) late eczematoid reaction. Types 1, 2 and 4 correspond to those described by Sulzberger and Wise (1932) and Type 3 has been added on account of its frequent occurrence in the strongly positive group. Type 1 was occasionally seen in the negative group and according to Bray is due to tissue damage at the site of injection. The results were read at intervals of one, two, four and seven days and were classified according to the following table.

Classification	Date of First Appearance	Maximum Duration of Weal	Urticarial	Delayed Reaction
Strongly	1st-3rd	10-20 mm	—	—
Moderate	1st-3rd	10-20 mm	—	—
Weak	1st-3rd	10 mm	—	—
Negative				

The trichophytin when fresh appears to be remarkably resistant to heat as five positive and five negative cases retested after autoclaving the extract gave the same results. A summary of the investigation is set out in tabular form below.

Type of Case	No. of Cases	Strong Reaction	Moderate Reaction	Weak Reaction	Negative Reaction
(A) Microscopically proved tinea	2	14	2	2	4
(B) Control with previous history of tinea	20	3	3	13	5
(C) Control with negative history	6	2	1	11	25

Owing to the difference in the numbers of cases in the three groups it is proposed to scrutinize the table as it stands and not in terms of percentages. The four negatives in Group A are disappointing but all of those cases showed "mosaic" fungi microscopically. According to Weidman (1936) such "mosaics" are either a stage in the development of fungus or are due to some fungoid action on the superficial layers of the dermis, while Whitfield (1935) regards them as artefacts due to interaction between the epidermal scales and the caustic potash used in preparation of the microscopical specimen. Repeated attempts to culture scales showing such "mosaics" were made under ideal conditions in Ramsbottom's mycological laboratory without success. Their exact nature, therefore, must be a matter for doubt, but it is of interest to note their frequent association with the accepted type of fungus. The results in Group B are gratifying, but the unavoidable personal error in assessing the history makes it difficult to draw a definite conclusion, and this becomes especially noticeable in Group C. Many patients may have had a patch of superficial tinea not diagnosed as such, or an interdigital type may have escaped notice completely. The frequency of such previous infections has been regarded as negating the value of a positive reaction (Wise and Wolf, 1936), and this would seem to increase considerably the value of a negative reaction.

### Conclusions

From this small series and from observation of the skin tests in other hands, it is permissible to state that a strong reaction in a clinically suggestive case with a negative previous history lends a bias towards a diagnosis of tinea, while a negative reaction in a similar case precludes a positive diagnosis completely.

An interesting outcome of the investigation was provided by two negative reactors in Group C. Some time after testing they developed microscopically proved tinea pedis—one with an associated tinea cruris—and when retested three weeks and twelve months after infection gave a strongly positive result.

### Summary

Attention is called to the increasing frequency of pedal tinea in America and to the large number of statistical investigations published by American observers.

The lack of comparable figures in this country is noted, and appears to be due to non-appreciation of the condition among the great mass of the profession.

The difficulties and pitfalls of diagnosis are described and a conservative opinion by Ramsbottom is quoted.

The case for diagnostic dermal tests with fungus extracts is set forth and the results of some previous investigations are given.

An investigation is described and the results given in tabular form.

The limitations of a positive result are noted, and the value of a negative result in the differential diagnosis of pedal skin lesions is stressed.

Grateful acknowledgments are due to Surgeon Captain C. M. R. Thatcher and Surgeon Commander R. A. W. Ford for permission to use their cases; also to Miss F. L. Stephens for her cultural work and to Mr. T. J. Shields for his assistance with the references.

## Clinical Memoranda

### Pneumococcal Meningitis Treated with Prontosil Soluble

The case recorded below appears to afford further evidence of the efficacy of prontosil in the treatment of pneumococcal meningitis, and presents in addition several other points of interest.

#### CASE RECORD

A girl aged 5 years was admitted to hospital on February 22, 1938, with a provisional diagnosis of meningitis. For the past three weeks she had been suffering from whooping cough.

On examination she was found to have a generalized purpuric rash, chiefly marked on the abdomen and limbs. There was rigidity of the neck muscles and head retraction and a tendency to opisthotonos. Photophobia was present and Kernig's sign was strongly positive. The lungs apart from a few catarrhal signs, appeared normal, and there was an apical systolic murmur. The temperature was 101° F., the pulse rate was 160 and the respirations 30. Haematuria was present. The child was very lethargic and wore an expression of frowning discomfort.

Lumbar puncture was performed and the cerebrospinal fluid was found to be slightly turbid and under considerable pressure. The result of pathological examination was as follows: Cells 11,200 per cmm (all polynuclear); chloride 816 mg per ccm; protein 150 mg per ccm; sugar absent; globulin reaction positive. Pneumococci in direct smears and on culture.

Owing to the difference in the numbers of cases in the three groups it is proposed to scrutinize the table as it stands and not in terms of percentages. The four negatives in Group A are disappointing but all of those cases showed 'mosaic' fungi microscopically. According to Weidman (1936) such "mosaics" are either a stage in the development of fungus or are due to some fungoid action on the superficial layers of the dermis, while Whitfield (1935) regards them as artefacts due to interaction between the epidermal scales and the caustic potash used in preparation of the microscopical specimen. Repeated attempts to culture scales showing such "mosaics" were made under ideal conditions in Ramsbottom's mycological laboratory without success. Their exact nature, therefore, must be a matter for doubt, but it is of interest to note their frequent association with the accepted type of fungus. The results in Group B are gratifying, but the unavoidable personal error in assessing the history makes it difficult to draw a definite conclusion, and this becomes especially noticeable in Group C. Many patients may have had a patch of superficial tinea not diagnosed as such, or an interdigital type may have escaped notice completely. The frequency of such previous infections has been regarded as negating the value of a positive reaction (Wise and Wolf, 1936), and this would seem to increase considerably the value of a negative reaction.

### Conclusions

From this small series and from observation of the skin tests in other hands, it is permissible to state that a strong reaction in a clinically suggestive case with a negative previous history lends a bias towards a diagnosis of tinea, while a negative reaction in a similar case precludes a positive diagnosis completely.

An interesting outcome of the investigation was provided by two negative reactors in Group C. ## Clinical Memoranda

### Pneumococcal Meningitis Treated with Prontosil Soluble

The case recorded below appears to afford further evidence of the efficacy of prontosil in the treatment of pneumococcal meningitis, and presents in addition several other points of interest.

#### CASE RECORD

A girl aged 5 years was admitted to hospital on February 22, 1938, with a provisional diagnosis of meningitis. For the past three weeks she had been suffering from whooping cough.

On examination she was found to have a generalized purpuric rash, chiefly marked on the abdomen and limbs. There was rigidity of the neck muscles and head retraction and a tendency to opisthotonos. Photophobia was present and Kernig's sign was strongly positive. The lungs apart from a few catarrhal signs, appeared normal, and there was an apical systolic murmur. The temperature was 101° F., the pulse rate was 160 and the respirations 30. Haematuria was present. The child was very lethargic and wore an expression of frowning discomfort.

Lumbar puncture was performed and the cerebrospinal fluid was found to be slightly turbid and under considerable pressure. The result of pathological examination was as follows: Cells, 11,200 per cmm (all polynuclear); chlorides, 816 mg per ccm; protein, 150 mg per ccm; sugar absent; globulin reaction positive. Pneumococci in direct smears and on culture.

The patient was given 10 ccm of prontosil soluble intra-muscularly twice daily on four successive days. At the end of this period the temperature and pulse rate fell to normal; the rigidity began to diminish and the child became less lethargic. The purpuric rash faded and the haematuria subsided.

Lumbar puncture was repeated on March 15. The cerebrospinal fluid was still under slight pressure and examination gave the following result: Culture sterile after twenty-two hours incubation. Cells 100 lymphocytes per c.c.m. Sugar present chlorides 725 m. per c.c.m. Globulin Nonne Apelt and Pandy reactions both negative. Protein 0 m. per c.c.m.

The patient made a complete and uneventful recovery and was discharged from hospital on March 29. Although the case presented several unusual features there can be little doubt that the basic condition was a pneumococcal meningitis and the response to treatment was of such a character as to justify the assumption that recovery was largely brought about by the injections of prontosil.

## Mechanical Obstruction of Ileum by Appendix

The following case, which came under my care at the Victoria Hospital, Swindon, seems of sufficient interest to be placed on record.

**Clinical History.**—The patient, a red-haired fair-skinned boy aged 13, was admitted to hospital complaining of pain in the right iliac fossa. Two years ago he had a similar attack which subsided under conservative treatment. On January 6, 1935, about 7 a.m. pain began suddenly in the right iliac fossa and he later felt sick and vomited. The pain was of an acute colicky nature and gradually got worse. He vomited repeatedly all day. In addition he had slight dysuria. His appetite was normally good and he was not constipated. Apart from the common complaints of childhood and jaundice when he was eleven years old his previous health had been good.

On examination the abdomen was seen to move slightly with respiration. Tenderness was marked a little below McBurney's point and was associated with hyperaesthesia and slight rigidity. On rectal examination no mass could be felt but he was extremely tender on the right side of the pelvis. Examination of the other systems revealed no abnormality.

**Diagnosis.**—The case was considered to be one of acute appendicitis although it was thought to be by no means typical—inasmuch as (1) the pain started in the right iliac fossa (2) the patient vomited repeatedly (3) the point of maximum tenderness was unusually low in the right iliac fossa.

**Operation.**—The abdomen was opened through a right gridiron incision and a distended and congested loop of small bowel was delivered through the wound. This was the terminal loop of the ileum which was tightly and completely encircled by a large appendix the tip of which was adherent to a tuberculous lymph node in the mesentery of the small intestine close to the root of the appendix. The appendix itself was congested and the lymph node to which it was adherent showed softening. After freeing the appendix along its whole length appendicectomy was performed and the obstructed loop of bowel was seen to empty immediately into the caecum. A number of lymph nodes were seen in the mesentery of the ileocaecal angle, one of these had caseated. The abdomen was closed without drainage.

Pathological examination of the appendix showed it to be congested and no evidence of tuberculous infection was found.

I am indebted to Mr J. Ewart Schofield, F.R.C.S., for permission to publish this case.

## Reviews

### GRAFTON ELLIOT SMITH

*Sir Grafton Elliot Smith: A Biographical Record & his Collections.* Edited by Warren R. Dawson, F.R.S.E., V.P.R.S.L., F.S.A. (Pp. 272, 3 illustrations, including a frontispiece, 12 6d. net.) London: Jonathan Cape Ltd. 1933.

Beyond any question Elliot Smith was one of the most remarkable personalities that have appeared in modern medicine. I have written medicine but a man so seen from the names of the men who have contributed to his biography, his zest for knowledge carried him far beyond the wide limits of the profession to which he was bred. The editor of the biography, Mr. Warren R. Dawson, who contributes a summary of the activities in which our great anatomist crowded his life, is not a medical man; he was one of the many young men of inquiring mind who perceived the fertility of the methods which Elliot Smith began to apply to the study of Egyptian civilization at the end of the nineteenth century, leading to conclusions which so startled and upset more orthodox scholars. Dr. W. J. Perry, who contributes a chapter on Elliot Smith as an anthropologist and ethnologist, is another early recruit who too up and extended lines of inquiry which arose from Elliot Smith's work in Egypt. Elliot Smith had this essential mark on his character: he had not only the vision to see the advance of knowledge was possible but also the inclination as to the way by which that advance could be attained. Then there is another non-medical chapter on the life of Lord Rutherford (a brief but invaluable chapter) dealing with the life which two young adventurers from the Dominion—first one from New Zealand the other from New South Wales—led in the University of Cambridge in 1896 when Elliot Smith arrived there.

The other chapters are written—and extremely well written—by anatomists. Professor J. T. Wilson, his master—it is a genius like Elliot Smith can be said to name a master—writes of early years in the University of Sydney; a chapter which leaves no doubt, in the mind of the reader that so far as Elliot Smith is concerned the boy was father to the man. Then follows a chapter on Professor Wood Jones who now occupies the chair of anatomy in the University of Manchester. Professor Wood Jones thus fills a position which was held and made famous by the man whom he brings so vividly to life in these pages. Professor Wood Jones joined Elliot Smith in Egypt and deals with the most fertile phase of the master's career. Then follows the important Manchester phase from 1899 to 1919 which is described by the pupil who succeeded him in Manchester, Professor J. S. B. Stoptford, now Vice-Chancellor of the University. The account of his life at University College London, the final phase of a wonderful career, has fallen into the able hands of a former colleague at University College, Dr. H. A. Harris, now professor of anatomy in the University of Cambridge. A summary of his career as an anatomist is contributed by Dr. A. J. E. Cave of the Royal College of Surgeons of England. Thus all phases of Elliot Smith's career have been covered and a picture has been drawn which future generations will certainly wish to possess.

Not the least valuable section is a complete bibliography; the items numbered 34—books, monographs, articles and reviews being included in the list. Elliot Smith served no period of apprenticeship in his career; like all first-class men he began his career (1874) with

a mature and finished piece of work—a research on the commissures of the mammalian brain. Being in contact with Professor J. T. Wilson, Almroth Wright, and C. J. Martin in those early years in Sydney, he acquired from them the best technique then available for microscopical work on the brain—more than students could then obtain in England. It was certainly Elliot Smith who introduced into British Anatomy modern methods of brain research. His predecessors approached the problems of the human brain by giving their attention to the form and size of its outer aspect, whereas Elliot Smith's intuition led him straight to its deepest and oldest parts—the commissures and the olfactory bulb and lobe. His predecessors began with the human brain and then worked down the animal scale, he began low down in the animal scale and worked upwards, and so came by a clear perception of the sequence of events which ended by giving man his predominant brain.

From 1894 to 1907 papers on the brain came in rapid sequence. In 1907 new items began to appear on his list of literature. He had then been teaching anatomy in the medical school at Cairo since his arrival in Egypt in 1900. Until 1907 he resolutely refused to be drawn from his prescribed course of brain research. Circumstances proved too strong for him. We find him becoming involved in the study of the ancient Egyptians—first of their bodies and then of their civilization. With most men a "new love" means a break with the "old love." But this was not so with Elliot Smith, he added subject to subject, and kept a "harem" of research going with ease.

The places held by Lord Rutherford and Sir Grafton Elliot Smith have been "filled," but their successors would be the last to claim that they had replaced them. Both advanced knowledge, both had the power to impart their gifts of mind to apt pupils, yet I feel persuaded, and the study of this life of him by old comrades and pupils has deepened my conviction, that coming generations will be interested in Elliot Smith not because of his discoveries, but because of the man he was—a man of a rich, peculiar, and lovable personality. I might have quoted passages from Stopford, Wood Jones, or H. A. Harris to bring out this personal aspect of his life, but I have refrained, leaving the enjoyment of these passages to the readers of Elliot Smith's biography.

ARTHUR KEITH

## INJURIES OF THE EAR

*Traumatismes de l'oreille*. By J. A. Ramadier and R. Causse. (Pp. 150, 15 figures. 45 fr.) Paris: Masson et Cie. 1937.

In their small volume on injuries of the ear Dr. Ramadier and Dr. Causse group the subject-matter under four headings: (1) injuries of the external ear, tympanic membrane, and middle ear; (2) fractures of the temporal bone; (3) gunshot wounds; and (4) concussion of the labyrinth. They provide in addition a description of the examination both clinical and pathological, required for medico-legal report or evidence.

A most important section deals with the light which has been thrown upon fractures of the skull by histological examination of the petrous portion of the temporal bone. Fractures of the temporal bone can be roughly divided into longitudinal and transverse varieties, while the oblique combines some of the characters of both, the longitudinal variety being the more common. In the longitudinal variety the line of the fracture descends from the squamous portion of the temporal bone across the tegmen tympani and middle ear and then passes along the anterior aspect of the pyramid. The tympanic mem-

brane is ruptured, but the internal ear and the facial nerve escape injury. The transverse variety is a fracture of the labyrinth and passes across the cochlea, and often the facial nerve is injured either at the internal auditory meatus or in the aqueduct of Fallopius. The inner or labyrinthine wall of the middle ear may be injured, but the tympanic membrane remains intact.

Nager has shown histologically that in transverse fractures the capsule of the cochlea may be cracked like an eggshell from such an injury, although there is no naked eye evidence of the fracture. If the patient recovers from a longitudinal fracture no dangerous sequel is to be feared, but after a transverse fracture the barrier between the middle ear and the internal ear is permanently impaired. Even a mild attack of otitis media is then liable to extend through the internal ear to the meninges. Thus a longitudinal fracture, which tears the tympanic membrane, is associated with some immediate risk of intracranial infection, whereas a transverse fracture with intact tympanic membrane puts the cavity of the tympanum into communication with the subarachnoid space at the internal auditory meatus, and heals in such a way that for the rest of his life the patient is in danger of meningitis should the middle ear become infected. The interval in recorded cases may be as short as twenty-eight days (Scheibe) or as long as fifteen (Brocq) or even sixteen (Schlittler) years, but the sequel is now proved to be a direct though remote consequence of the original injury, not a mere coincidence, and such a conclusion has been accepted by insurance companies. The information contained in the book might have been provided more concisely, but the matter is readable and is of prime importance in relation both to the management of head injuries and to the problems of compensation which arise later.

## RENAL DISEASE

*Practical Talks on Kidney Disease*. By Edward Weiss, M.D. (Pp. 176, 3 figures, 12 tables. 9s.) London: Baillière, Tindall and Cox. 1937.

Professor Edward Weiss of Philadelphia has made a useful summary of his reading and practice in a series of practical talks on renal disease. An attack of glomerulonephritis while a resident at hospital led him to take a special interest in the subject, and his experience with himself and his patients has enabled him to produce a handy volume which is informative and stimulating. He begins by traversing the old disputes between clinicians and pathologists, and traces the development of the modern concept of renal disease. The chief function of the kidney is the removal of waste products from the blood, at the same time preventing the elimination of certain vital substances. In addition it has much to do with the regulation of the water balance and maintenance of the acid-base equilibrium of the body. Kidney disorders lead to some degree of interference with renal function, but there is no selective impairment of renal function. In chronic renal disease the kidney, by means of its reserve capacity, can compensate for a disturbance of its function with increased work. It is important to recognize that impaired renal function is a decompensation and that failure may be brought about by extra-renal factors—diarrhoea, vomiting, active perspiration. The methods of assessing the efficiency of renal function are numerous. Not all are needed, in early cases the 11th recommends the modification of the concentration test suggested by Fishberg—specimens of morning urine obtained after taking no fluid after 6 p.m. the previous day. An impaired kidney cannot concentrate up to a 1:1000

gravity of 1023. In advanced chronic renal disease the non-protein nitrogen of the blood is the best index of renal failure.

The various groups of kidney disease are discussed on orthodox lines but the author is not afraid to state his own views. On the question of protein in the diet he insists that there is no need for restriction in glomerulonephritis except at the beginning and end of the disease; his remarks on the treatment of uraemia are practical; the nephritic oedema of the earliest stages and the nephrotic oedema of the subacute stage must be differentiated from the cardiac oedema of the final stages of chronic glomerulonephritis (small white kidney). On the subject of nephrosclerosis the author states that too much may be made of the effort to bring down the blood pressure. The patient with high blood pressure and perhaps albuminuria who is referred to as a cardiovascular renal case may be suffering from (1) cardiac disease with renal congestion (2) nephrosclerosis (3) chronic glomerulonephritis or (4) a combination of these processes. Progress in this subject is impeded by a failure to differentiate them. A series of plates beautifully illustrates the eye grounds and vascular changes in this group of diseases. Unfortunately numerous misprints sometimes the omission of a word make reading difficult and indicate hasty proof-reading. These detract from the pleasure of handling a well-informed book on renal disease.

### THE STEROL GROUP

*Sterols and Related Compounds. A Series of Three Lectures delivered at the Institute of Biochemistry, Cambridge.* By Professor E. Friedmann, M.D., Ph.D. With a Foreword by Sir Frederick Gowland Hopkins, O.M., F.R.S. (Pp. 100, 7s. 6d. net.) Cambridge: W. Heffer and Sons, 1937.

These lectures were delivered by Professor Friedmann in 1936. Sir F. Gowland Hopkins in a foreword points out the rapid development of the importance of the sterol compounds for both chemistry and biology. As always happens in such cases the mass of resultant literature is such as to make it inaccessible to all but specialists and hence an authoritative review on the subject is of great general value. The sterol group includes substances with an extraordinary variety of important physiological and pharmacological actions. This variety is fully indicated by the chapter headings which read: sterols, bile acids, heart poisons, saponins, vitamin D, sex hormones and carcinogenic agents. Even this list does not exhaust the activities of sterol derivatives since the same group also includes the adrenal cortex hormone, vitamin E and the organizers which regulate development in embryonic tissues.

The author treats the subject from the chemical aspect and gives a brief but lucid account of the brilliant researches whereby the relationships between these different groups have been established. The order of the complexity of the subject is indicated by the fact that irradiation of ergosterol produces at least six different derivatives, only one of which (calciferol or vitamin D<sub>2</sub>) is antirachitic while antirachitic principle of fish liver oils (vitamin D<sub>3</sub>) is yet another related compound. Similarly the author describes seven different forms under the general term follicular hormone. Facts such as these indicate the intricacy of the problems with which he deals. The chemistry of this group is of exceptional importance from many points of view and it is particularly important to medical science because advance in this field is the only hope of obtaining a number of important

hormones and vitamins in quantities adequate for general clinical use.

The volume is short (100 pages) but is liberally illustrated with structural formulae. The reason for its brevity is indicated by Sir F. Gowland Hopkins. The author has the gift of conveying clear and adequate information in the fewest possible words. The book contains, I believe, no single redundant sentence nor one unnecessary word.

### LEGAL MEDICINE IN AMERICA

*Legal Medicine and Toxicology.* By Thomas A. Gonzales, M.D., Morgan Vance, M.D., and Milton Helfern, M.D. (Pp. 744, 24s. 6d. net.) New York and London: D. Appleton-Century Company, 1937.

Medical jurisprudence in the sense of the science of criminal necrology is practical or nothing. It grows in the unsavoury soil of the mortuary and flourishes in large and turbulent cities. These authors have for years been investigating violent, sudden and suspicious deaths in the police department of New York. Few better opportunities could be imagined for acquiring a familiarity with the victims of suicide, murder and accident. In the city of New York the medical examiner's office investigates about 15,000 deaths every year. Since 1918 when the coroner was abolished it has investigated over a quarter of a million deaths. The authors are pupils and close associates of the late Dr. Charles Norris, the first chief medical examiner of the city and form one of the most famous teaching organizations for legal medicine in the world. They are therefore excellently qualified to write a classical textbook and they have written one which may well be adopted in all English-speaking countries as a guide to the solution of medico-legal problems of every kind. Its bias is naturally upon criminology, but no part of the science is neglected.

Toxicology is treated in a separate section and from a practical point of view. The various poisons are dealt with in separate chapters under their main headings—for example, poisonous gases, corrosives, metals and salts—and their analyses are treated in detail in three more chapters. The authors discuss in close detail the routine work of the medico-legal expert and the section on blood grouping is full and up to date. The rights and obligations of physicians are taken rather shortly, but adequate attention is given to the medical side of insurance and compensation. There is probably more to be said about forensic psychiatry than the authors say in six pages, but into those six pages they have compressed much valuable information. Briefly the book has no gaps and hardly a word is superfluous. It is beautifully classified and the detailed table of contents almost makes the index superfluous. Its most striking feature is its enormous number of excellent photographs, mostly of corpses in various stages of decomposition or mutilation. One drawback is the immense weight of the volume, perhaps due to the demand of the half-tone blocks for a heavily loaded paper.

### Notes on Books

In his small book *Failure of the Heart and Circulation* which is one of a series termed Pocket-Monographs on Practical Medicine, Dr. TERENCE EAST has by the use of an epigrammatic style and the complete exclusion of padding succeeded in comprising more real information than is contained in some large textbooks. The modern views on the mechanism, types and causes of heart failure are given not in any detail but so that the student may understand the principles, and symptoms are likewise dis-

cussed in the light of recent work on pathological physiology. The relatively long section on treatment is an admirable summary of essentials, though it is difficult to understand the author's luke-warm approval of digitalis for failure with normal rhythm. There are occasional other points on which cardiologists might differ, but as a whole the book gives the student and practitioner a sound outline of cardiology presented in the best way—that is, on the basis of physiology. In spite of the terse style it is clear and readable. The publishers are J. Bale, Sons and Curnow, and the price is half-a-crown.

*The Baths of Bath in the Sixteenth and Early Seventeenth Centuries* is a little book by P. ROWLAND JAMES, M.A. (J. W. Arrowsmith, 5s). Visitors to Bath are so accustomed to think of the city as a beautiful town peopled by the brilliant company known to Jane Austen that Mr. Rowland James has done good service by describing its rise. It was a small-walled city in the reign of Henry VIII inhabited by cloth-workers, the baths were negligible, and spa treatment had not yet come into vogue. A hundred years later William Turner, Doctor of Medicine, Dean of Wells, and a great botanist, Dr. Jorden, and Toby Venner had drawn attention to the baths. Anne of Denmark, Queen of James I, Charles I, and Henrietta Maria visited them, their reputation was made, and the cloth-workers became keepers of lodging houses. Mr. Rowland James tells the story of the change, going to original documents for his facts and illustrating them with maps and copies of old engravings. Appendices contain a list of distinguished visitors to Bath from 1573 to 1624, among them are Queen Elizabeth, the Earl of Essex, Sir Walter Raleigh, Thomas Howard Earl of Arundel, and many others. There is a record of the companies of players who were present in Bath between 1569 and 1617, and a hand-list of the manuscripts and principal works consulted.

Dr. E. P. STIBBE's *Introduction to Physical Anthropology* (Edward Arnold, 10s. 6d.) has satisfied an urgent demand for a short book giving the necessary information for field workers in anthropology, and the new edition of his manual, which has been fully revised and enlarged, will be very welcome. The general trend of the first edition has been maintained—namely, a clear account of the aims and scope of physical anthropology combined with detailed information of just those points which it is necessary for a non-professional worker to know. The new edition includes an excellent elementary account of modern statistical methods by Dr. W. A. M. Smart, some new illustrations, and a considerable amount of recent information on anthropological discoveries, such as the newly found skulls of *Manthropus*.

A new paper (No. VII) by John R. Baker, M.A., D.Phil., lecturer in cytology in the University of Oxford, on *The Spermicidal Powers of Chemical Contraceptives: Approved Tests* is now available from the office of the National Birth Control Association, 69, Eccleston Square, London, S.W.1, price 6d., post free 7½d.

Dr. WALTER RUHMANN of Berlin issues a translation into German of the *Liber de Rheumatismo et pleuritide dorsali* which appears appropriately enough at a time when rheumatism is attracting general attention. The original treatise was published in Paris in 1542 by Biliarius (1538-1616), one of the great teachers of the French school of medicine. Biliarius, known to his contemporaries as Guillaume de Baillou, was urgent that medicine should go back to Hippocratic methods and was thus in some sort a forerunner of Sydenham in our own country. Dr. Ruhmann, in addition to the translation supplies an introduction, an appendix, and a list of the works consulted. He also reproduces a pleasing engraving of Biliarius at the age of 43. The book is published at Mittenwald by Arthur Nemayer, price RM. 1.80 or RM. 3 bound. It is entitled *Das Rheumabuch des Doktor Biliarius*.

## Preparations and Appliances

### INDUCTION SPECULUM

Mr. A. LEECH-WILKINSON and Dr. D. A. MITCHELL (Bath) write

This instrument has been devised for the special purpose of induction of labour by the Drew Smythe catheter method, or by simple puncture of the membranes without anaesthesia. It has been found particularly useful in multiparae, in whom the voluminous folds of the vagina are apt to bury the ordinary Sims speculum and prevent vision of the cervix, which may be situated high up behind the total head. The distal (cervical) end of the instrument is exactly

the same width as the ordinary Sims speculum but shallower, from this point backwards it broadens generously to its proximal extremity, the sides being deepened and the length increased. A retractor type of handle is employed as giving the best command of the blade and, with the patient in the left lateral position, the clip of the light carrier lies on the inner aspect of the upper side.

The instrument has been made for us by the Holborn Surgical Instrument Company, Ltd., 26, Thieves' Inn, London, E.C.1.

### HOMOGENIZED INFANTS' FOODS

Libby's homogenized baby foods (Libby, McNeill and Libby, Ltd.) represent an interesting advance in infant feeding. Vegetables, fruits, and cereals are treated by a special method which breaks down the cells and subdivides fibres into fine particles. The material is thus reduced to a fine powder, which can be digested in the absence of the enzymes necessary to break down vegetable cells.

The manufacturers provide pamphlets which report on an extensive series of laboratory and clinical experiments. Vitamin assays showed a high vitamin content. *In vitro* tests with digestive enzymes showed a rapid conversion of starch to lower carbohydrates. X-ray examination showed that homogenized vegetables left the stomach about four times as quickly as did strained vegetables. A dietary study of seventy infants showed that homogenized vegetables did not cause gastro-intestinal disturbance and prevented the development of nutritional anaemia.

The makers claim that these homogenized preparations make it possible to supply infants with vegetables at the age of three months. The introduction of these preparations would appear to constitute an important advance in infant feeding and the manufacturers are to be congratulated on the care with which they have organized exhaustive tests of the properties of their products.

## ANTE-NATAL CARE AND SOME COMPLICATIONS OF LABOUR

BY

D. J. MacRae, M.B., F.R.C.S.D., M.C.O.G.

*Obstetric Registrar St. Mary's Hospital*

It is commonly understood that the first stage of labour begins with the establishment of uterine contractions. It would however be of greater benefit if it were considered that this stage began during the last few weeks of pregnancy with the formation of the lower uterine segment and a slow moulding and reconnoitring of the presenting part into the most acceptable pelvic position. At this time there arise also in the patient's mind those vague doubts and fears which it not allayed may influence injuriously the course of labour. It is during these latter weeks too that many fundamental decisions are made and skilled guidance given which will have a profound effect on the ultimate labour.

### Pelvic Measurements

It is well to obtain a mental picture of the physical and sexual development of the patient before beginning the examination of the pelvis. A short squat figure and absence of femininity often reflects a similar lack of female characteristics in the bony pelvis and may be associated with indifferent pains at parturition. Knowledge of the external pelvic measurements alone is of little value and the teaching that the foetal head is the best pelvimeter is but partially true. There are cases with normal external measurements in which internal examination may reveal a jutting sacral promontory or undue prominence of the ischial spines. Again cases are seen in which the foetal head cannot be made to engage in the pelvis although an easy labour may ensue or in which the head may engage but labour be prolonged and even difficult. If a foetal head passes through the pelvic inlet it should likewise in the great majority of cases pass through the outlet. Yet experience shows that many such cases are liable to end in stillbirth. Minor degrees of pelvic contraction while permitting delivery may so delay descent or initiate uterine inertia that there is a prolonged and dangerous compression of the foetal head. It is only by means of a careful examination of the pelvic cavity and outlet that such difficulties can be foreseen. Routine internal examination educates the fingers to the normal pelvic roominess and permits estimation of the available space in the anterior and posterior segments of the pelvis so that when any abnormality is encountered it is readily appreciated.

Gauging the width of the subpubic angle is difficult and requires practice but the posterior segment can readily be measured. The method of Caldwell and Mollov is preferable to that of the estimation of the posterior sagittal diameter. In the former the distance between the sacrum and the ischial spine is measured along the sacro spinous ligament and in the normal female pelvis this should accommodate three fingers. With a normally curved sacrum a shorter measurement here suggests a small sacro sciatic notch conforming with that found in the male type of pelvis in which delay of the head at the outlet is liable to occur. When as often happens with this kind of pelvis the head has engaged in a posterior position the narrowing outlet may lead to a failure in rotation and result in the typical deep transverse arrest of the foetal head. The smallness of the subpubic angle also leads to outlet delay the occiput finds difficulty in slipping below the pubic arch and if the perineum is firm an episiotomy or the application of forceps to the low-lying head will be necessary.

### Position of the Foetal Head

A careful palpation is made of the abdomen to reveal the position of the foetal head. In the majority of cases

it will be found lying in the transverse diameter of the pelvic inlet with the occiput to one or other side and in patients with a normal pelvis and development no difficulty is to be expected at parturition. A posterior position of the occiput on the other hand is sometimes associated with an abnormal pelvis and especially one with male tendencies. At one time Buisson pads were used to induce an anterior rotation of the occiput and Herrman practised an external rotation of the head and body. Such methods however are neither sufficiently successful nor are they always indicated in certain types of pelvis. It is normal for the head to descend in a posterior position. If immediate correction is undertaken it is usually found at the next ante natal examination that the foetal head has reverted to its previous position. The majority of cases ending as they do successfully for mother and child are hence at this stage best left alone. When in the absence of pelvic abnormalities or tumours the foetal head is found in the latter weeks of pregnancy in an abnormal position—in the fundus or iliac fossa—and being corrected persists in moving away from the lower pole of the uterus a low insertion of the placenta may be suspected. Such patients may well be treated on the lines of those suffering from ante partum haemorrhage and be admitted to hospital for the appropriate investigations.

### The Non engaged Head

There is no manoeuvre better suited for demonstrating whether a non engaged head will or will not enter the pelvis than that used by Fahmy. With the index finger and the thumb exerting pressure upon the occiput and sinciput respectively the patient is asked to sit upon the examination couch. On doing so unaided her abdominal muscles tighten often pressing the foetal head into the pelvis. If however the head does not descend with digital pressure as may happen in the patient with an increased pelvic inclination an additional manoeuvre can be attempted. The patient is made to lean as far forward as possible relaxing the abdominal muscles and thereby enabling the uterus to fall more into line with this less vertical axis of the pelvic inlet. Then digital pressure often causes the head to enter the pelvis with an ease and spontaneity which is at once surprising and comforting. Any overlapping of the foetal head on the symphysis pubis is readily appreciated at this time by the palm of the examining hand which can feel simultaneously the foetal head and the pubes.

Some of the cases of non engagement of the foetal head left to have a trial labour belong to the class with increased pelvic inclination. The quick descent of the head which is so often seen after rupture of the membranes in these cases can be understood. The head resting uneasily upon the pelvic brim when labour starts allows the liquor amnii freely to escape below it with each contraction there is therefore in the early stages of labour a failure of descent of the foetal head. The bag of waters meanwhile allows of a slow taking up of the cervix but as soon as the external os begins to dilate there is the risk of rupture of the membrane. With the membranes ruptured the uterus is able to push directly on the foetus usually causing the head to enter the pelvis in the position of anterior asynclitism. Good contractions and the direct pressure of the foetal head allow the thin lower uterine segment and the os to be pulled up and dilated.

### The Patient's Mental Attitude

There is no physiological process in which the mental attitude of the patient exerts a more profound influence than during pregnancy and labour. Its effects in inducing pathological conditions and serious mental disturbances are well known and it is equally important to recognize the physical effect this mental attitude can produce in relation to the actual birth of the child. There is no greater error than to omit to treat especially in primigravidae incipient fears and misgivings. Furthermore, a

# ONE HUNDRED AND SIXTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION PLYMOUTH, 1938

**T**HE one hundred and sixth Annual Meeting of the British Medical Association will be held in Plymouth next summer under the presidency of Dr Colin D Lindsay, senior physician to the Prince of Wales's Hospital Plymouth. He will deliver his address to the Association on the evening of Tuesday, July 19. The Sectional Meetings for scientific and clinical work will be held on Wednesday, Thursday, and Friday, July 20, 21, and 22, the morning sessions being given up to discussions and the reading of papers. The Annual Representative Meeting for the transaction of medico-political business will begin on the previous Friday, July 15. The full list of presidents, vice-presidents, and honorary secretaries of the seventeen Scientific Sections, the provisional programme and time-table, information about accommodation, and other details of the arrangements for the Annual Meeting were published in the *Supplement* of April 9. We publish below the third of a series of descriptive and historical articles on Plymouth. The first and second articles appeared on January 1 (p. 32) and March 5 (p. 518).

## DEVON AND CORNWALL

Few counties can compare with Devon and Cornwall for richness of scenery, the chief characteristic of which is probably its vivid contrasts. Compare that vast tableland of Dartmoor with its rugged tors, its wide expanses of sparse moorland, its tumbling streams and its panoramic views, with the winding lanes in the softer lowlands leading to the coast, flanked by high hedges in brilliant greens of grass and fern, and gemmed with a rich variety of wild flowers, which thrive in profusion. Again, compare the romantic cliffs of North Cornwall, those huge natural battlements presenting passive yet impregnable resistance to the never-ceasing onslaught of Atlantic rollers, with the quiet retreat of Dartmeet, where two rivulets born among the crags of the moor join forces on their journey to the sea, 'making sweet music with their enamelled stones'.

Beauties are here for visitors to enjoy, and excursions have been arranged to enable them to appreciate all that the two counties have to offer. Any who are interested in history or in archaeology as well as natural beauty will find much to appeal to their tastes. The West is rich in both. This may be judged from some of the salient features of places to be visited.

EXETER CATHEDRAL

(Henry Wykes Exeter by courtesy of Corporation of City of Exeter)

## Exeter

Exeter is the county town. Parliamentary and municipal borough, seat of a bishopric, head of an archdeaconry, a city and shire with its own sheriff and under-sheriff, and a county borough. Its situation is both picturesque and commanding and it is a notable fact that from prehistoric times it has maintained unbroken its position as the local capital. Long before the Roman invasion it was the most ancient of British cities, and though the Roman dominion ceased early in the fifth century, it became the head of Damnonia and the chief city of the West. When its recorded history began towards the close

of the ninth century it was the leading city of the West Saxon kingdom. The origin of its municipal constitution is not on record, although it was presumably governed by reeves. Its first charter was granted by Henry II, and it elected parliamentary representatives as far back as 1264.

Exeter preserves much of the past and yet is up to date, possessing fine modern buildings and old historic houses. A magnificent and venerable pile is the Cathedral with its bold and massive design, rich in the decorated tracery of its windows. Of its original erection nothing is known. A local historian of the sixteenth century said there were within the precincts of the close three religious houses:

a nunnery—now the Deans' house—and two monasteries, one founded in 868 and the other in 937. The Chapter House dates back to 1224 and the Cathedral register to 1194 but the episcopal register contains entries from 1255. The peal of bells is stated to be the heaviest in England. One large bell, known as Great Peter and weighing over 55 tons, was presented to Bishop Peter Courtenay in 1480. The Guildhall, another notable building, was built in 1310 and re-erected in 1464. Rougemont Castle, at one time a fortress, stands on a rocky eminence on the north angle of the

city wall, two hundred feet above sea level. The corporation possesses many treasures: there is a fine museum as well as the up-to-date buildings of the University College of the South-West.

## Torquay

From whatever point of vantage one looks down on Torbay, Torquay is always a beautiful sight. To-day the space called Torbay is covered with water, and this has been its condition for thousands of years, but such has not always been the case. At least twice previous to the luxuriant forests have flourished here where now the sea

ebb and flow. Geologists can point out the raised beaches indicating its former possession by the sea and any day at low water relics of the more recent forest may be seen on the Torre Abbey sands.

In 1588 one of the captured galleons (the *Capitana*) of the so-called invincible Armada was brought into Torbay and her soldiers and sailors placed as prisoners in the tide barn of Torre Abbey. Their memory still haunts the place for it has been called 'The Spanish Barn' ever since. In 1685 the Prince of Orange afterwards William III came here and landed at Brixham whence he marched to Exeter on his way to London. The Jacobite Duke of Ormonde sailed into the bay in 1715 with the object of raising Devonshire on behalf of the Pretender but as no response was made to his signals he sailed back to France. During the wars preceding and accompanying the French Revolution Torbay was the place of assembly for a long succession of fleets. Maritime war preparations were constantly present until the arrival of Napoleon on board the *Bellerophon* in 1815 after which beyond the occasional appearance of a few warships peace descended on these waters.

It was during these French wars that Torquay began to grow. A ship would be ordered to Torbay to await the arrival of her consorts and might be lying there for months before the requisite complement to form the fleet was assembled and nearly all our celebrated admirals, including Nelson, St Vincent and Howe came here hoisted their flags and sailed away. The coming of these strangers encouraged the natives to build a few small houses to accommodate them and their families. Very few of these families lacked an ailing member and it was soon apparent that many of these benefited by their stay in Devon so the beginning of Torquay's climatic reputation may really be ascribed to the French wars.

Every visitor must be struck by the beauty of Torquay. The town is built on a series of hills on which are innumerable villas each in its own well wooded garden. The view of the town from the sea is really enchanting.

Leaving Torre Abbey and following the coast line there is a long panorama of beautiful buildings, hotels and villas and the terraces and architecture give the impression of an Italian seaside town. The town is built round the harbour and it is interesting to see the water so close to the principal thoroughfares especially when the water is dotted with boats and yachts. The flowers give ample testimony to the mildness of the climate. Even in February one can see out of doors the flower

of the magnolia blooming beside the crimson camellia. The aloes flourish easily and so do flax, myrtle, bamboo and various sorts of palm.

There is an idea among those who do not know Torquay that because the climate is mild in winter it is hot in summer but this is fallacious. Torquay is built on a promontory dividing Paignton from Babbacombe. The surrounding water of Torbay together with the breezes from the hills tend to keep this resort cool. The advantages of so equable a climate so much natural beauty and such ample provision for the entertainment and comfort of visitors make Torquay most suitable for physical treatment and it is fortunate in possessing a splendidly equipped modern marine spa under the control of the corporation staffed by fully certified assistants. It possesses too in the Meadfoot Spring a water having medicinal value.

#### Other Historic Beauty Spots

**Moretonhampstead** on Dartmoor near the eastern border was originally a borough by prescription and formerly governed by a Portreeve. The annual courts at one time held by the Earl of Devon have been

discontinued. A typical moorland town its link with the past may be judged from the fact that its Charter for the market and two fairs was obtained by Hugh de Courtenay in 1335. The Church of St Andrew built in the Perpendicular style has two good pieces of granite in the stained glass windows. The church register dates from 1603. George Parker Bidder the famous calculator and engineer a friend of George Stephenson, was born here in 1806.

TORQUAY LOOKING WEST FROM VANE HILL  
(Re produced by courtesy of the G.W.R. Company)

POLPERRO  
(Western Morning News Co. Ltd. Plymouth)

have set us fine examples in the patient ascertainment of data bearing on the question of heredity. In the immense volume of effort devoted to the study of cancer in this country a place should be found for this analytical type of research on the broader basis which the "follow-down system" would require.

## HEALTH IN PUBLIC SCHOOLS

The public schools of England, their good points and bad points, have been discussed by innumerable writers, great and small, particularly during the last century, we do not think, however, that as a class they have been the subject of a Stationery Office publication since the Royal Commission of 1864, when girls did not sport old school ties. Elsewhere in this issue we print a brief abstract of a Stationery Office publication—*Epidemics in Schools*—which is concerned with that aspect of public school life of special interest to our profession. It is a valuable document, the historical introduction to which is pleasant reading in these pessimistic times, because the contrast between hygienic conditions now and even a century ago is great, and it is made plain that the public spirit of the medical profession has been a powerful factor in the improvement.

The main object of the report, which is an interim report, is to give a precise account of the frequency and severity of disease, particularly infectious disease, in the schools. Although the period of observation is only five years, the data are so extensive that, so far as concerns the age and sex incidence of sickness and the attribution of time lost through sickness to various diagnostic groups, it is unlikely that further data would modify the impression conveyed. Differences as between particular schools and as between boys and girls in the aggregate are striking. Sometimes an obvious explanation suggests itself. That minor nasopharyngeal infections—coughs, colds, and sore throats—should have a heavier statistical incidence upon girls than upon boys and upon younger than upon older children is not surprising, girls are likely to be looked after more sharply than boys, and young children are under closer supervision than the dignitaries of the sixth form. Why there should be a contrast in the incidence of serious illnesses such as otitis media, pneumonia, and acute rheumatism is less obvious. No doubt here, too, closer supervision plays its part. Again, droplet infection in sleeping quarters may be hindered by the greater use of cubicles or separate bedrooms in girls' schools. But the general problem is unsolved. Particular attention was given to the

dynamics of the common epidemic diseases. Here also are unsolved problems. Scarlet fever was introduced many times, but there are only eight instances of ten or more cases, and in the largest outbreak (twenty-five cases) only 3 per cent of those not previously attacked took the disease. It is common knowledge—the historical introduction gives specific instances—that in the days of our grandparents scarlet fever was a scourge of schools. The low fatality of scarlet fever now may perhaps be attributed to a change of type in the infecting organisms. How far this explains the low infectivity in school experience and to what extent improved sleeping accommodation and closer medical supervision are responsible are questions not yet satisfactorily answered. Turning to a directly practical matter, we note that the report expresses some fear that tonsillectomy is becoming a routine measure and doubts whether "this mass attack upon one of the normal structures of the body was justified." This is a subject upon which there is much to be said, the conclusion reached and the evidence upon which it is based deserve careful attention.

The committee has done pioneer work in epidemiological research and has had to fashion a new technique. Unlike psychological novelists, who make so many lurid discoveries in our public schools, it has no sensational results to record. The scientific pioneer does not expect to reach El Dorado in a day's journey: indeed if that city seemed to have been reached so soon he would know it to be a mirage. To the general reader perhaps even to the medical reader, this volume of 288 pages may not seem of much interest. Probably few readers of the *Philosophical Transactions* 250 years ago gave more than a glance at Halley's Life Table or realized that a new organon had been forged. A page or two of figures are not exciting, many pages are soporific. Yet this report may perhaps date a new epoch as surely as did Halley's Table. It is the first example of pure co-operative research in the field of school hygiene. We do not undervalue the immensely important work of the national school service, that deals with numbers of young lives in comparison with which the statistics of all the public schools are puny. But this smaller population is mainly a boarding-school population, a set of semi-isolated groups the epidemiological history of which may in the long run provide solutions for fundamental problems of group disease. Hence we should be grateful both to the committee and to its numerous collaborators. The first stage of a long journey has been completed—a journey which will gradually increase knowledge of epidemiology in general and the hygiene of youth in particular.

## HORMONAL REGULATION

The growth both of interest and of knowledge of the hormonal regulation of the body is exemplified by the publication of the reports presented to the

Journées Médicales de Paris Internationales for 1937<sup>1</sup>. They form a volume of 850 pages, contributed by chemists, biologists and clinicians most of whom have been engaged in active research on the subject in different countries. Professor Carnot's introduction is perhaps somewhat of the nature of a rhapsody, but he rightly emphasizes the part in this advance that has been played respectively by work on the chemical structure of hormones, histological studies of the glands themselves, clinical observation and particularly by the recognition of the mutual interplay between nervous and glandular mechanisms. All this has led to a much more accurate conception not only of the integration of the endocrine system but of the integration of the body as a whole. Even more, endocrinology is seen to have relationship with carcinogenic substances, vitamins and vegetable auxins, thus taking its appropriate place in a scheme of general biology.

Nothing has done more to clarify our views on the endocrine system than the realization of the manifold functions of the hypothalamus. Itself the mechanism controlling the expression of the emotions, it has ties on the one side with the cerebral cortex and on the other with the vegetative nervous system. In addition to this it is in such close relations with the pituitary body anatomically and physiologically that one may justifiably speak of a unit—the hypothalamic-pituitary apparatus. Indeed the nervous portion of this apparatus has even been observed to take on secretory functions after ablation of the glandular portion. This apparatus thus falls into line with the general law that nervous mechanisms operate through chemical intermediaries, or as Hopkins phrased it, chemical substances locally produced interpret for the tissues the messages received from the nerves. Doubtless the endocrine glands exert an autonomous activity of their own, here as Professor Loeper says in his admirably balanced summing up, they work in silence and in secret. But we now see as we did not at first, that this is only one half of the story. For through the sympathetic and parasympathetic, and also through the moderator action of the anterior pituitary, the whole endocrine system can be influenced by the central nervous system and mobilized for the benefit of the body as a whole. It is of course also true that the glands in their

turn can influence the activities of the central nervous system.

All this and more is fully discussed in these reports starting with Dr Roussy's article entitled 'Neuro-hormonal and Hormono-neural Regulation' but it is impossible to do more in the space at our disposal than to indicate the general trend of the discussions by this brief paraphrase. We must however call attention to Professor P. E. Smith's short communication in which he deals with the great difficulty of visualizing the existence of such a large number of hormones as separate entities as has been claimed for the anterior pituitary. He finds a partial solution in the variations in the receptivity of the structures on which these hormones are called upon to act. This is the other side of the problem: the nature of the hormonal stimulus has been intensively studied as these reports bear witness, but the study of the way in which the tissues receive the stimuli and differentiate between them has hardly begun.

## THE FLAVINE ANTISEPTICS

There has recently been correspondence in this *Journal* on the merits and uses of acriflavine which was of interest in reviving a long standing controversy dating indeed from the days of the war. This discussion was concerned simply with acriflavine itself but acriflavine is only one of several antiseptics similar in composition and in action. The best known of these are rivinol (ethoxydiaminoacridine lactate), proflavine (2,8-diaminoacridine sulphate) and those antiseptics which consist of a mixture of 2,8-diaminoacridine and its methochloride. A mixture of these substances in the basic condition is known under the names of euflavine, tryptaflavine and neutroflavine, while a mixture of the corresponding hydrochlorides is acriflavine. The proportions in these mixtures are undefined and variable, hence the desirability of identifying a single substance having merits at least equal to those of the best samples of acriflavine. As in so many other fields of therapeutic research, by no means all related compounds, any of which may possess a similar and perhaps superior action, have been synthesized and it is important that the properties of new compounds should be placed on record even if they are not of outstanding merit, since such extension of knowledge allows useful conclusions to be drawn on the general relationship between chemical constitution and biological action. A. Albert, A. E. Francis, L. P. Garrod and W. H. Lunnell<sup>2</sup> have now reported the synthesis of ten new acridine compounds together with a study of their biological properties from the points of view both of their capacity for killing or restraining the growth of bacteria and of their power to damage the body. From their results it appears that the science of antiseptics is far more complex than is generally imagined, an intri-

<sup>1</sup> Les Régulations Hormonales en Biologie, en Clinique et en Thérapeutique. Paris: J. B. Baillière et Fils, 1938, 100 fr.

cate series of differences in effect is revealed, some of which have important bearings on clinical application. For example, of the bacteria tested *Streptococcus pyogenes* is decidedly the most susceptible to the action of all acridine antiseptics, *Ps. pyocyanea*, on the other hand is unaffected by any of them, which means that one common type of wound infection is quite outside the scope of this treatment. The frequently quoted observation that serum actually enhances the antiseptic effect of acriflavine—instead of diminishing or even abolishing it, as is the case with agents of other kinds—is confirmed only to a limited degree and for the bacteria (which do not include *St. pyogenes*) with which Browning originally observed this effect. Tests of toxicity by two methods in some cases gave contrasting results, it appears that a compound may be more lethal than another to the whole body, but at the same time less lethal to leucocytes, and this difference no doubt reflects a varying susceptibility of different tissues, corresponding to the similar variation observed among bacteria. These facts would influence the choice of an antiseptic for different purposes, one being more suitable for local application to a wound on account of its harmlessness to leucocytes, another for internal use, as in treatment aimed at the urinary tract, on account of the tolerance to it of the body as a whole. The main conclusion emerging clearly from this study is that the more efficient of these compounds will stop the growth of bacteria, or even kill them, in spite of the presence of blood or serum, in concentrations which do not prevent the activity of leucocytes as judged by either motility or the phagocytosis of bacteria. In this their claim is unique, and no class of antiseptic has a better title to be regarded as the ideal prophylactic, particularly against streptococcal infection. There is all the difference in the world between prophylaxis and treatment, the former is still the province of old-established antiseptics, while the purposes of treatment, for which antiseptic applications have never been really satisfactory, are now likely to be better served by other means.

### ENZYME CHEMISTRY

Professor Carl Oppenheimer continues to work steadily at his task of summarizing recent advances in the huge subject of enzyme chemistry. During the past year he has brought out four more parts of the supplement to his encyclopaedic work on ferments and their action.<sup>1</sup> These parts complete the study of the proteases deal with the desmolases and begin the study of the zymases which cause the breakdown of hexose. Among the proteases considered are trypsin, pepsin, and thrombase. The outstanding advance recorded in the matter of trypsin and pepsin is their isolation in crystalline form by Northrop. Thrombase and blood coagulation occupy sixty pages but although numerous minor advances are recorded few major discoveries have been made recently in this subject. The section on the

desmolases opens with a review of modern ideas on the mode of oxygen uptake by cells a subject that has developed very rapidly during the past few years. These enzyme systems are of dominant importance in biology, since they supply the energy which maintains the activities of the great majority of living forms. The uptake of oxygen by cells appears to be effected by chain processes, each process is complex, and several parallel mechanisms exist even in a single cell. The complexity of the subject is indicated by the fact that a tabular summary of the known hydrogen and oxygen "acceptors" occupies five pages. Oxidative mechanisms have lately engaged particular attention, and knowledge in this field has advanced with exceptional rapidity, the general result has been to reveal enzyme systems of a hitherto unsuspected complexity. It seems probable that an equal complexity will be found in other fields of enzyme activity when these are examined with equal care. The living cell is forced to work under very strict limitations as regards variations of temperature, osmotic pressure, etc., and these limitations appear the probable cause for the remarkably complicated nature of biological enzyme processes. This general tendency towards complexity rather than simplicity adds much to the difficulty of enzyme chemistry, and is one of the primary causes for the enormous output of writings on this subject. Oppenheimer's encyclopaedic work is the only comprehensive guide to this literature and is of corresponding importance.

### BEE VENOM FOR ARTHRITIS

Tradition has it that bee-keepers are immune to rheumatism, and the sting of bees has for long been a popular remedy for sufferers from this disease, though it has only been employed by the medical profession during the last half-century. Since bee venom became available in a purified form its use by intradermal injection has grown more popular. The idea that the beneficial effects were due to formic acid was accepted for a long time, but recent research has shown that the explanation is less simple and that the action is analogous to that of snake venom. As with so many remedies, the value of published observations has been impaired by the unscientific way in which much of the work was carried out. The cases have not been carefully selected and defined, and controls have not been used. In such a disease as rheumatoid arthritis, which varies so much in severity and in which periods of improvement or quiescence often occur under favourable conditions without any special treatment, the difficulty of assessing the value of any remedy is great. Recently Kroner and a group of colleagues working in the medical department of Cornell University have carried out observations<sup>1</sup> on 100 patients. They were divided into three groups: in the first the disease was of an active and advanced type, in the second condition was less severe but characteristic features were present—usually fusiform swelling of the

<sup>1</sup> *Die Fermente und Ihre Wirkungen*. By Professor Carl Oppenheimer. Parts 6, 7, 8 and 9 of Supplement. The Hague: D. W. Junk. (10 Dutch florins each.)

joints in the third group there were no objective signs but there was complaint of pain in and tenderness of the joints. In all three there was an increased sedimentation rate. Definite improvement was observed in seventy three patients and seventeen were entirely free from symptoms six months to a year later. Naturally the proportion of improved cases was greatest in the least severe type but benefit was experienced by six out of the ten most severe cases with an improvement in the sedimentation rate also. No controls were used but the results were compared with those obtained in a series of 103 patients treated by other observers (for example by tonsillectomy and the administration of a haemolytic streptococcal vaccine) improvement was noted in 58.3 per cent. It must be noted that Kroner chose for the most part patients who had previously had a focus of infection removed and in his statistics does not distinguish these from those in whom tonsillectomy was thought to be contra indicated. All the patients were ambulatory they were prescribed cod liver oil a diet rich in vitamins and heat to the joints and to this regime undoubtedly some part of the improvement must be attributed. The importance of rest and measures for the improvement of the general health without any specific treatment is shown by the results which were published by Pemberton. He reported a series of 300 cases treated in this way so effective was it that in a considerable number no other treatment was found necessary. The lesson is obvious but a good case has been made out for a careful trial of treatment by bee venom in suitable cases.

### THE MIDWIFERY SERVICE

The report on the work of the Central Midwives Board for the year ended March 31 1937 has been published by H.M. Stationery Office price 4d. The period under review was one of far reaching development in the midwifery service in England and Wales. It may perhaps be regarded by future generations as approaching very near in importance the year 1902 during which the first Midwives Act for England and Wales was placed on the statute book and the foundations were laid for the establishment of a well ordered properly trained profession of midwives. The report gives statistics of the number of women on the Roll of Certified Midwives (65 046) and of those in practice (16 648). The number actually engaged in the practice of the profession was thus little more than a quarter of the total. Of the midwives enrolled 63 543 were trained women. A report of the examinations held both for pupil midwives and for midwives who wish to train pupils is included together with notes of various decisions by the Board on midwives' training etiquette and practice. During the year under review the Minister of Health approved the revised training and examination rules on the preparation of which the Board had been engaged for a considerable time. The two most important changes effected by the new rules are (a) an extension of the period of midwifery training both for trained nurses and for other pupil

midwives and (b) the division of the course of training into two parts each of which will be completed by an examination those successful in the second being awarded the certificate of the Board and admitted to the Roll of Midwives. Rules have also been framed and submitted to the Minister of Health for approval regulating the post certificate courses for practising midwives in accordance with the provisions of the Midwives Act of 1936. An important decision during the year was the permission given to midwives to administer nitrous oxide and air to women in childbirth under certain conditions. On the subject of teachers and teaching the report says

In the firm belief that the generally desired further improvement in the standard of skill and proficiency of midwives cannot be effected until there is an adequate supply of teachers possessing not only skill in the practice of midwifery but also teaching ability of a high order the Board has devoted special attention to the question of how best to secure quickly sufficient teachers of the type required. Almost without exception the midwives who are responsible at the present time for the instruction of pupil midwives are most skilful midwives but unfortunately the most skilled practitioner is not always the best teacher. Some of the existing teachers do not possess any real aptitude for teaching others would become good teachers if they were given the opportunity of receiving proper training in the difficult art of teaching. The main problems before the Board have been (i) how to discover the midwives who possess a natural aptitude for teaching and (ii) how best to instruct such midwives in teaching methods.

While the Midwives Act was in preparation and when it was before Parliament the Central Midwives Board had opportunities of conveying to the Minister of Health its views and suggestions on the various provisions. It is in complete sympathy with the aims of the Act and is confident that its provisions can be made the basis of a material improvement in the efficiency of the midwifery service. The Board has studied closely the requirements of the new domiciliary service of whole time midwives and the effect of its establishment on other branches of the Board's statutory duties. At the end of July the headquarters of the C.M.B. were removed to larger premises at 23 Great Peter Street Westminster S.W.1.

### FOOD POISONING FROM MILK

An outbreak of gastro-enteritis at Wilton in Wiltshire due to ingestion of contaminated raw milk is described in a report issued last week by the Ministry of Health.<sup>1</sup> The outbreak involved about one hundred individuals mostly school children on October 28 and 29 1936. It followed consumption of the milk at an interval of twelve to twenty four hours and was characterized by headache nausea vomiting and later by diarrhoea accompanied in some instances by much dehydration and collapse. The stools were frequent and watery but contained neither blood nor mucus. The diarrhoea lasted for one to three days. Pyrexia of 99° to 103° F. in the initial stages was commonly noted all the patients made rapid recoveries. Food poisoning from

<sup>1</sup> Report on an Outbreak of Food Poisoning due to *Salmonella* Type 'Dublin' and Conveyed by Raw Milk. Ministry of Health London 1938.

ingestion of preformed toxins, such as the toxin of *Staphylococcus aureus*, was thought unlikely, since a shorter interval—some three to four hours—is a characteristic feature of that condition. On the other hand, the absence of mucus and blood from the faeces and the rapid subsidence of symptoms were points against bacillary dysentery. Bacteriological examinations of the faeces were not carried out until six days after the onset and yielded negative results in every instance. From a specimen of the suspected milk on the second day a *Salmonella* organism, later identified as a "Dublin" type was isolated, and four days afterwards a sample of milk from the same producer yielded a similar result. Confirmatory evidence that this was the causative organism was provided by the finding of high-titre specific agglutination of the organism by the serum of nine of the children during convalescence. The serum of three out of fifty-one cows showed the presence of specific agglutinins but three examinations of milk were negative. On the other hand the dung of one of these three cows repeatedly gave positive results. Although the blood of one of the workmen at the distributing dairy gave a positive agglutination reaction, the evidence pointed to the conclusion that he was a victim rather than the cause of the outbreak. Investigation revealed that, owing to certain defects in the technique of operation of the mechanical milking-plant, contamination of the milk could have occurred. Reference is made in the report to outbreaks of enteric fever, scarlet fever and streptococcal tonsillitis in recent years, in all of which the infected milk had passed routine bacteriological standards for cleanliness. It is hinted that gastro enteritis or "summer diarrhoea" in children may sometimes be attributable to milk or other food contaminated in this way. The main conclusion to be drawn from this particular outbreak is that all milk should be efficiently pasteurized before being passed on to the consumer. The objection usually advanced against general application of this measure has lost any weight it had since it has been established beyond doubt that there is no significant difference in the nutritive values of raw and pasteurized milk.

### CONFIDENTIAL CERTIFICATION OF DEATHS

In the February issue of the *Quarterly Bulletin* published by the Health Department of the City of New York (vol vi, p 16) reference is made to a new procedure to secure confidential certification of the causes of death, worked out by Mr J Duffield and approved by committees of the New York Academy of Medicine and the Five County Medical Societies. The certifying practitioner will be asked to furnish two certificates: one contains only a general statement of the cause of death—for example, "natural cause", the other is a confidential report to be handed in a sealed envelope to the undertaker and to be transmitted by him to the Department of Health. This latter document must not be copied, the open certificate alone may be copied for legal or insurance purposes. Over an experimental period the new forms will be limited to the boroughs of Manhattan and the Bronx, so that the

continued use of the old form of certificates in Brooklyn, Queen's, and Richmond may serve to test the value of the change. The experiment will be watched with interest. The details are not quite clear. It is stated that the name, age, sex, nativity, address, and other identifying particulars will appear on the open certificate. Presumably age, sex, nativity, and occupation will be required for the tabulation of the confidential data. We believe that in the Swiss system anonymity is secured by transmission to the Central Statistical Department unopened of a confidential report which does not record the name or address of the deceased. In fact the local registration official himself never sees the confidential particulars. The essence of such a system is absolute security against leakage.

### THE INCISION FOR APPENDICECTOMY

In November, 1934, among correspondence in the desk of the late Dr L L McArthur of Chicago was found a letter from Charles McBurney, written from Highgate Springs, Vermont, and dated October 10, 1894. Now in the John Crerar Medical Library of Chicago, this is a reply to a letter Dr McArthur had written on August 24 of that year congratulating McBurney on the account of his muscle-splitting incision, which had appeared in the *Annals of Surgery* for July, 1894. With it Dr McArthur had enclosed a copy of a paper describing the same incision, which he had been about to present to a meeting of the Medical Society of Chicago in the previous June. He had been unable to do so because of the length of the agenda at that meeting. Dr S W McArthur of Chicago describes this example of two men converging on the same line of work at the same time and unknown to each other. McBurney wrote of the muscle splitting incision: "I think it is destined to supplant all other operations for the removal of the normal or of the chronically inflamed appendix." To-day it is also widely used for appendicectomy in acute cases and has its supporters the world over. Mr W H Bowen of Cambridge, however, reserves the McBurney method of approach for appendicitis complicating pregnancy and in most cases prefers the pararectal incision introduced by the late W H Battle of St Thomas's. Mr James Sherrin and other surgeons have been equally ardent advocates of the paramedian incision. These three incisions—the McBurney, Battle's, and the right paramedian—probably constitute the practice of the great majority of surgeons. Each has its advantages and disadvantages which are influenced by both the type of patient and the stage and type of the disease. Most surgeons of experience will probably agree that no one incision is to be slavishly adopted for all cases.

At the statutory meeting of the Royal College of Physicians of London held on Monday, April 11 Dr Robert Hutchison was elected President in succession to Viscount Dawson of Penn.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## THE TREATMENT OF MINOR CONDITIONS IN THE EYE

BY

N. BISHOP HARMAN, F.R.C.S.

Conjunctivitis may be one of the minor diseases of the eyes, but it may be so severe as to constitute a major emergency and endanger the sight.

The conjunctiva is the delicate mucous membrane lining the inside of the eyelids and the exposed part of the eyeball. It is moistened by the mucin from its epithelium and by the tears which pass from the lacrimal gland embedded under the outer prominence of the brow to the puncta at the inner canthus and so down the tear duct into the nose. Since the membrane is exposed to the dust of all the winds that blow and to touching by dirty hands it is liable to infection. The tears prevent many an infection both by washing the eyes and also by reason of a dissolving effect they have upon germs.

### Examining the Conjunctiva

It is easy to examine the conjunctiva lining the lower lid. It is not easy to do this for the upper lid and turnix unless the knack of everting the lid has been mastered. Yet the upper fornix is the more important by reason of its depth. To the practised hand the eversion is a simple and nice performance. Instruments should not be used; they alarm children. The lashes should not be employed as lifts; ladies dislike losing these adornments. All that is needed is the worker's own thumb and index finger and the patient's lower lid. Stand facing the patient. Use the right hand for the left eye and the left hand for the right eye. Tell the patient to look down. Place the inner edge of the thumb parallel with the lower lid and on its outer half a quarter of an inch below the lashes. Lay the inner edge of the index finger lightly on the upper lid just above the lashes and gently push up the skin; this will cause the edge of the lid to lift from the globe and pout a little. Now with the thumb in position slip the lower lid under the upper lid and the thumb following the lower lid, will get under the upper lid which can be held firmly between thumb and first finger and everted even against a vigorous orbicular spasm. The secret of the trick is to make the lower lid serve as a wedge to get under the upper lid.

### Conjunctivitis Irritant

The delicacy of the conjunctiva allows the classical signs of inflammation to be clearly noted: redness from distension of the vessels which since they have little support are apt to bleed, heat from the hyperaemia, swelling that may be a slight oedema or an intense chemosis rendering the lids and globe immobile and the skin of the lids glossy, and pain which is described as like grit in the eyes even to a severity as though broken glass were rolling under the lids. Besides these there is discharge consisting of excess of tears, frothy secretion from the Meibomian glands, mucin from the epithelium and escaped leucocytes. So there will be a muco-purulent, a purulent or a sanious discharge according to the severity of the attack. Vision is always disturbed.

Conjunctivitis may be caused by local or by reflex irritation. Mild attacks follow exposure to wind, dust, smoke, fumes or heat. Reflex irritation due to septic teeth, nasal douches, gastritis or the taking of stimulating foods will produce the symptoms. Exposure to bright light such as the arc lamp, ultra violet rays or snow fields in the high Alps will cause smart attacks known as snow blindness. Drugs—for example arsenic—are often excreted by the mucous membrane and if irritating will produce conjunctivitis. Tired eyes from late hours or errors of refraction cause mild attacks which if repeated may become chronic. In all these conditions discovery and removal of the irritant will be followed by improvement in the condition. The patient will be comforted by the use of a lotion of boric acid (2 per cent) in laurel water.

### Conjunctivitis Contagious

Conjunctivitis due to microbial infection is more common among children than among adults and among dirty ill kept folk than among those of cleanly habits. Two forms are common: (1) angular conjunctivitis, (2) pink eye. Angular conjunctivitis is a mild but chronic condition causing redness of the lids particularly at their angles whence the name angular. The ocular conjunctiva is but little affected. The secretion may contain minute bubbles so that it appears like frothed white of egg; this is caused by the excessive blinking of the lids. When the lids are screwed up the secretion is squeezed out at the angles where it erodes the surface epithelium of the skin. It is slightly more common with women than with men and in adults than in children. The cornea is rarely affected. The organism causing the disease is a thick square ended diplobacillus; it stains well with aniline dyes but is decolorized by Gram's treatment. It is easily demonstrated in film preparations and grows on dried serum slants liquefying the serum into deep sharp edged pools of turbid fluid. The treatment of angular conjunctivitis is simple: zinc sulphate is a specific which may be used freely either in 1% or 1.2 per cent strength as an eye lotion or better it may be dropped into the lower eyelids with a pipette. It is the success of zinc sulphate in the treatment of this disease that has made it almost a household remedy for eye troubles. But good as it is in this common form of conjunctivitis it may be noxious in other types of inflammation.

The most common epidemic form of conjunctivitis is that known as muco-purulent conjunctivitis. It is very contagious. If one member of a family is infected all the members are likely to be attacked. It is the common pink eye of schools. The occurrence of such an epidemic is a reflection upon the toilet arrangements of the home or school. The inflamed eyes show marked hyperaemia of the whole conjunctiva; there is a velvety look about the upper tarsal membrane and minute haemorrhages will be noted about the loosely supported vessels of the ocular conjunctiva. The lymph follicles of the lids are swollen and appear as slightly raised pinkish grey bodies about one half to one millimetre in diameter. The discharge shows pale greyish yellow pledgets of muco-pus floating in the tears and collected in the lower fornix and lacus lacrimalis. Commonly the attack begins in

one eye and then affects the other. Sometimes the preauricular gland is inflamed. In severe cases, such as are seen in Eastern countries, the discharge may be profuse and almost purulent sharp-edged crescentic ulcers, "catarrhal ulcers," erode the margins of the cornea and sight may be damaged by their effects. In England they are rarely dangerous. The organism known as the Koch-Weeks bacillus is rod-shaped, and is minute and delicate. In most of its features and reactions it is like *H. influenzae*—in fact, some workers have sought to prove that the organisms are one and the same.

The prevention of pink-eye in schools depends upon attention to toilet arrangements. Each child should have its own handkerchiefs, towels, and brushes; exchanges should be strictly prohibited. Exclusiveness in clothing, toilet, and sanitary articles is the basis of civilized cleanliness. On an outbreak of the disease in a school or family those affected should be isolated. The unaffected may be further protected by the use of eye drops of zinc sulphate 1/2 per cent morning and evening. The treatment of the disease should be initiated by the surgeon. The conjunctival sac should be washed out with boracic lotion and the everted lids, fornices, and particularly the folds of the inner canthus then painted with a solution of silver nitrate. The solution must be fresh; it works best and is less painful when it contains 20 per cent of glycerin. The strength of the silver salt in solution should be 1/2 or at most 1 per cent. The silver solution should be applied by the surgeon. He should not order it as 'drops' for the patient's own use. Patients have a habit of continuing treatment indefinitely. Silver salts if long used are absorbed and deposited in the elastic fibres of the submucosa so that the conjunctiva and cornea may become stained blue black (argyrosis). For the patient's own use a lotion of zinc chloride 1/8 per cent is beneficial, and in the stages of convalescence recourse to the zinc sulphate drops is good practice. In no circumstances should lead lotions be employed. Lead is readily absorbed by an abraded cornea and leaves a permanent white mark, which may obscure vision.

#### Ophthalmia Neonatorum

Purulent conjunctivitis is a severe and dangerous disease. In this country it is most often seen in infants. The eyes of the child are infected at birth by vaginal discharge. The gonococcus is responsible for the majority of the infections, but the streptococcus will produce disastrous results. Ophthalmia neonatorum usually begins about the third day after birth. The lids become red and swollen and their edges stick together. On opening them yellowish pus exudes. The everted lids show a rich velvety mucosa. The cornea may be affected by ulceration or it may slough with consequent incurable blindness. The disease is preventable. Gibson of Manchester in 1807 recommended that (1) the leucorrhoea of the mother ought, if possible, to be cured during pregnancy; (2) when this has not been done the noxious secretion ought to be removed from the vagina during delivery; (3) the infant's eyes ought, immediately after birth, to be cleansed with a fluid which either removes the noxious matter or is able to prevent its injurious effects. That is the treatment of to-day. The disease is notifiable. A purulent discharge from the eyes of an infant commencing within twenty-one days from the date of its birth must be notified (L.G.B. Order 1914). The measures taken to prevent and treat the disease have materially reduced the tale of blindness among children. They are

1 Directly the head of the infant is born wipe the eyelids dry with clean cotton-wool. Use a fresh piece for each eye.

2 As soon as the mother is settled wash the infant's eyelids freely with a simple lotion—boracic or Condy 2 per cent. Run the fluid freely between the lids. The water for the child's first bath must not get into its eyes. Separate water and a fresh towel must be employed for the infant's face. At no time may the mother's toilet articles be used for the child.

3 If at delivery there is a suspicion of a purulent discharge from the vagina of the mother cleanse the baby's eyes as suggested, then instil a drop of silver nitrate 1 per cent between the lids. The eyes must be examined and washed after eight hours, and if there is a suspicion of discharge make and stain film preparations for microscopic examination. The gonococcus is easy to demonstrate with methylene blue staining; the groups of biscuit-shaped cocci within the leucocytes are characteristic.

Treatment consists in (1) cleansing, (2) use of a germicide. Special nurses must be put in charge or the child should be taken into hospital, preferably with its mother. The surgeon in charge should never omit to examine and note down the state of the cornea as soon as he sees the case. The cleansing is the chief part of the treatment. The eyes should be washed free from pus every hour and irrigated every four hours with plenty of boracic lotion. Syringes and large irrigators are dangerous. Retractors should not be used. The lids should be parted with the fingers and the lotion run in from a cotton-wool swab or with an undine; the nozzle of which is protected with rubber tubing. The silver nitrate solution, 1 per cent, or other chosen germicide should be painted over the conjunctiva once a day by the surgeon. Gonorrhoeal conjunctivitis in adults is now very rare. It is usually due to the transfer of urethral discharge by the contaminated fingers. The symptoms are intense, and the danger to sight is grave. Such a case should be removed to hospital immediately.

In outlining the treatment of conjunctivitis painting the lids has been mentioned. Brushes should not be used for this purpose. They are rarely surgically clean and the hairs are apt to get loose. The surgeon should make a fresh cotton-wool brush for each eye treated. Take a wisp of cotton-wool about the size of a postage stamp and a tapered glass rod or a thin wax taper. Hold the cotton-wool between the tips of the left thumb and finger, press the end of the rod upon the wool, then lightly pinch the wool on to the rod and twist the rod at the same time. The wool will be securely twisted on to the rod.

#### Hyperaemia as a Diagnostic Symptom

Pink eye or hyperaemia, is a symptom common to many diseases of the eyes; it is therefore necessary to be able so to read other signs as to determine the real nature of the trouble. Three diseases may be named: acute conjunctivitis, acute iritis and acute glaucoma. All cause hyperaemia, pain and disturbance of sight. A liability will be some distinction. Conjunctivitis is not common in children, iritis in young adults, and glaucoma in elders. But the most valuable distinction is to be found in the state of the pupil. If the pupil is normal the disease is probably conjunctivitis; if the pupil is small and irregular it is probably iritis; if the pupil is enlarged slightly oval and immobile glaucoma may be present. When examination with a magnifying glass does not reveal the condition clear the test should be done with a mydriatic. Put one drop of 1 per cent homatropine within the lower lid of the eye and let the patient

with the eyes closed for half an hour. If then the pupil is found to be dilated evenly and well the condition is certainly not iritis. If the pupil has dilated but little and its outline is irregular there is iritis. If the pupil has dilated with almost alarming rapidity there is likely to be glaucoma, and then the mydriatic should be neutralized immediately with eserine. (Atropine should not be used for this test since it is such a powerful mydriatic that it cannot be neutralized by eserine.) Of all the means of differential diagnosis the state of the pupil is the most valuable and also the most objective.

#### Lacrimal Obstruction Infants

On occasions a baby will be brought for examination with the complaint that in eye has been inflamed since birth. The infant may be a few days to a fortnight old. The unwary may jump to the conclusion that this is a case of ophthalmia neonatorum. Examination of the eyes will show that the condition is quite different. First it will be noted that one eye is healthy and the other is in a messy state. The lid margins are clogged and mucus and pus hang about the inner canthus. When the discharge is wiped off with cotton wool the eye and lids will look healthy except that the conjunctiva will be too wet. If now the little finger be pressed down between the inner canthus and the nose the reason for the trouble will be shown: mucus pus will regurgitate from the lacrimal puncta. The trouble is due to obstruction of the lacrimal duct which carries the tears from the eye into the interior meatus of the nose. The lacrimal duct develops as an epithelial cord which becomes embedded in the nose and is then canalized. A plug of epithelial debris may block the duct.

#### TREATMENT

For a fortnight the effect of drops such as zinc chloride 1/8 per cent may be tried. The mother should be taught to increase the natural pumping action of the lid movements. The infant is laid on its back and some warmed lotion is poured into the hollow of the inner canthus. Now the lower lid is pulled outwards away from the nose; this brings the cord of the tensor tarsi into action and so opens the sac and sucks the lotion into it. The little finger is then pressed down on the sac the contents of which are forced down the duct. If this treatment fails the duct must be syringed through with plenty of fluid. One operation is usually successful. A general anaesthetic is needed. The lower punctum is stretched with a dilator a rod the size of a dance programme pencil with a tapered blunt pointed end. The dilator is pressed downwards into the minute hole of the punctum for one millimetre then the handle is depressed so as to be parallel with the lid margin and with a rolling movement the dilator is insinuated a little way into the canaliculus, so that both this and the punctum are stretched without being split. The nozzle of a lacrimal syringe is now passed in the same way first downwards then inwards until the nozzle can be felt pressing upon the wall of the sac against the nasal bones and lastly the body of the syringe is raised to lie alongside the nose with the nozzle pointing down the duct. The contents of the syringe are driven out. If the fluid passes into the nose it runs back into the throat, and the child will be seen to swallow.

#### Lacrimal Obstruction Adults

Epiphora or a watery eye is an annoyance. In certain walks of life it may be a real danger to the sight of

the eye. An interference with the muscular mechanism of the lids or the position of the puncta or any obstruction to the drainage apparatus will cause tears to flow over the cheek. It may be an after effect of facial paralysis or chronic blepharitis or of scarring of the lid. Obstruction in the duct is due to some nasal trouble. There may be disease of the nasal bones from syphilis; it has been known to follow periostitis arising from dental disease and it may be caused by fracture of the nose from falls or blows. In some cases nasal catarrh may spread upward into the duct and cause more or less temporary obstruction. Apart from the annoyance or the condition it is dangerous when it occurs in those whose work renders them liable to exposure to dust or flying sparks such as smiths or road makers. A septic tear will infect a corneal abrasion and a hypopyon ulcer with the loss of the sight of the eye may follow.

In any complaint of epiphora first note the position of the lids and puncta then test the patency of the tear passages. Place within the lower lid a fragment of dry fluorescein close the lids pinch the nose to make the tears flow then pump the tears down the duct (as described in the section dealing with the infant). If the passages are normal the stain will pass into the nose and can be blown out in a minute or so. If the stain does not come through the duct may be explored by (1) syringing (2) probing.

The method of syringing has been given above. In cases in which there is inflammatory swelling of the mucous lining of the duct regular syringing with hydrogen peroxide 3 volumes will often effect a cure. In cases of long duration where there is a mucocele in the sac and especially if the contents are purulent there is probably an organic stricture either of the bone or of the lining membrane. The suspected stricture should be searched for with a probe. Use a drop of cocaine and adrenaline. Then after dilating the punctum pass the probe as directed for the nozzle of the syringe. When the probe is in the duct slide it down gently until the stoppage can be felt. If it is elastic it is probably membranous; if it is tough and resistant it is probably bony. In the latter case there is no doubt as to the proper procedure. The sac canaliculi and the remnants of the duct should be extirpated by operation or a passage from the sac directly into the nose may be made by a plastic operation. When the stricture is probably membranous the decision as to treatment is more difficult. To force the stricture by probes and then leave it will be useless for the subsequent scarring will be denser than before. If the probe can be gently insinuated through some part of the stricture there is a prospect of success by long continued syringing. It is dangerous to syringe immediately after passing a probe a false passage may have been made and the syringing will drive the possibly septic contents of the tear passages into the cellular tissues and may set up acute cellulitis. A leaden style solid or hollow may be passed down the duct if a probe will dilate it sufficiently without force. The upper end of the lead is lipped over the lid to prevent it slipping down. Styles may be worn for months without discomfort but they must be removed periodically and cleaned. In most such cases it is better to remove the sac or make a direct passage into the nose. Some plastic operations succeed well though there may be trouble from the puffing up of the tissues when the nose is blown. After removing the sac and blocking the canaliculi the excess of tears gradually ceases and there is no inconvenience, except in cold winds or emotional states.

## EPIDEMICS IN PUBLIC SCHOOLS

## A STATISTICAL ANALYSIS

The committee whose interim report is now published<sup>1</sup> was appointed by the Medical Research Council eight years ago under the chairmanship of Sir George Newman, who when he retired was succeeded by the present Chief Medical Officer of the Ministry of Health, Sir Arthur MacNalty. The reasons which led the Council to take this step were, first, that much experimental work had been done—largely under the auspices of the Council—on the phenomena of infectious disease spreading in communities of mice and, next, that careful observations had been made and recorded of similar phenomena in a boarding school of a certain type. It seemed desirable, therefore, to test the analogies suggested by laboratory experiment and the findings of a particular set of observations of human beings, in a wider field—namely, a representative sample of British public schools.

The committee was fortunate in securing the co-operation of many schools, and this report is an account of the first five years' investigations. Section I (the work of Dr L. R. Lempriere, a member of the committee) is a most interesting historical account of the hygienic conditions of various great public schools through the ages. In the next section is described the elaborate system of recording adopted in the twenty-one boys' schools and ten girls' schools which participated. The average numbers per term under observation were 10,270 boys (8,287 of these in boarding schools) and 3,503 girls (3,061 of these in boarding schools). In all, 22,166 boys and 7,600 girls came under observation for one or more terms. Sections III to XIX treat of special clinical groups—namely, nasopharyngeal infection, sore throat, rheumatism, otitis media, sinusitis, pneumonia, influenza, tonsillectomy, infectious diseases, the relation between chicken-pox and herpes zoster, gastro-intestinal disorders, appendicitis, jaundice, tuberculosis, trauma, conjunctivitis, and tinea cruris.

## Method of Analysis

The general method of analysis may be illustrated by the lay-out of the chapter on nasopharyngeal infection. For this survey the diagnoses influenza, sore throat, cold, P.U.O. and chill, and cough were chosen; these are also shown as totals, two totals being given—namely, including and excluding influenza (a very large contributor). First we have a general table of attack rates for boarding schools (sexes, of course, shown separately), then tables of terminal attack rates and of weekly rates (boarding schools), a number of graphs, and rates for separate schools. Finally, the records of boys (in six schools) under observation continuously for at least three years are analysed with the object of discovering whether boys who suffered much (or little) from colds at, say, the age of 13 had a heavier (or lighter) incidence of colds at the age of 16. It was found that no relation could be proved to exist between the records—that is, what happened at 13 exerted no influence on what was to happen at 16. This method of arrangement is, so far as practicable, followed in the subsequent chapters, so that it will be sufficient to refer later to striking results noted in the general summary. Section XX very briefly refers to mortality. Since only forty-two boys and eight girls died this section is a mere matter of record. Section XXI is a very complete account of time lost and sickness in age-groups both for the whole population and individual schools—a most valuable piece of documentation. Section XXII (by Dr F. Griffith, a member of the committee) reports bacteriological findings. Thus of 199 instances of otitis media and mastoid disease the organism was not determined in sixty; in eighty cases *Str. pyogenes* (type

was determined in sixty-one) and in fifty-nine a pneumococcus (type determined in forty-seven) were responsible.

## Illness Rates in the Sexes

In Section XXIII—a general summary—it is first noted that, as the data were limited to illnesses which caused at least one day's absence from school, the great difference in rates in boys and girls for minor respiratory illnesses might be due rather to stricter surveillance than to greater susceptibility. A similar possibility has to be considered if the decreasing attack rate with age is attributed to natural immunization. It might be that younger children are more likely to be kept out of school than the older and less strictly supervised pupils. Only the accurate reporting of every cold, whether causing loss of school time or not, would tell us to what extent natural immunization is operating, and we gravely doubt whether there is any practicable method of obtaining such data. Not only influenza but many other diseases (otitis media, pneumonia, sinusitis) have a maximum in the Lent term. Trauma among boys is maximal in the Christmas term when general sickness rates are usually low (although the gastro-intestinal group is highest in that term). Among boys 90 per cent of infectious diseases (measles, German measles, chicken-pox, whooping cough, mumps, scarlet fever, and diphtheria) are equally divided between the first two terms of the calendar year; among girls more than 60 per cent of the cases were in the Lent term.

The ability of infectious diseases to work themselves out before the end of term varied greatly. About half the epidemics of measles may be said to have come to a natural end, but no epidemics of German measles and few epidemics of mumps, chicken-pox, and scarlet fever could be said to have ended before the holidays began. "It is impossible to explain this phenomenon on any theory dependent on the number of susceptibles exposed to risk, since examination of an adequate sample shows that about 70 per cent of public school boys have had measles, chicken-pox, and whooping cough before entry, about 30 per cent have had German measles and mumps, and less than 10 per cent have had scarlet fever, the corresponding figures for the girls are somewhat lower but of the same order. One might say that with an almost unlimited supply of susceptibles—usually 70 to 90 per cent—outbreaks of German measles, mumps, and scarlet fever might be expected to drag on until the end of term, but there is no obvious reason why epidemics of measles should tend to behave differently from those of chicken-pox in this respect, since the proportion of susceptibles is approximately the same—about 30 per cent—for these two diseases."

## The Question of Artificial Immunization

It is remarked that while one may be excused to regard those who have not passed through a clinical attack of measles, German measles, chicken-pox, and mumps as "susceptible" this can hardly apply to scarlet fever. In one school 30 per cent of 366 boys (out of 429) were found Dick-negative and about half the entrants in subsequent terms. The test has proved relatively reliable in the hands of many workers who used it as the object of artificially immunizing positive reactors. In view of the fact that scarlet fever has never attacked more than 3 to 4 per cent of the not previously attacked, this experience, it is doubted whether the advantages of artificial immunization in a public school outweigh the disadvantages. With regard to the relation of chicken-pox to herpes zoster, it is shown that on eighteen out of twenty occasions when zoster preceded chicken-pox, the first case of chicken-pox might from the point of view of time have arisen out of the case of zoster. The data of influenza disregarding the experience of a school show no evidence of an actively acquired infection lasting for as long as a year.

<sup>1</sup> Medical Research Council Special Report Series, No. 227. H.M. Stationery Office (4s. 6d. net).

## Influence of Tonsillectomy

About half the population was found to have had the tonsils removed and the proportion so treated was increasing. No satisfactory proof that tonsillectomy as a routine measure diminished the incidence of nasopharyngeal infections was obtained. Though reducing the value of the operation in carefully selected cases we have grave doubts as to whether the majority of tonsillectomies performed to day are the result of true disinclination rather than of routine ritual. The difficulties of interpreting sex differences have already been mentioned but the greater stringency of reporting could hardly account for differences in such serious infections as *etitis media*, pneumonia and acute rheumatism: the two former are more than twice and the last eleven times as frequent among boys as among girls. Closer supervision of minor illness and less close contact in sleeping quarters are possible factors. We believe that it is of the utmost importance that every effort should be made to discover the underlying cause of this fundamental difference in experience between the sexes so that the boys may if possible be freed from this heavy incidence of diseases which always cause anxiety and may produce serious disability or even death.

ROYAL MEDICAL BENEVOLENT FUND  
ANNUAL MEETING

The annual general meeting of the Royal Medical Benevolent Fund took place on April 5 with Sir Thomas Barlow its president in the chair. The financial statement was presented by Dr I. G. Glover, the honorary treasurer, who said that subscriptions and donations were up by £1,739 as compared with the year before, but legacies had fallen by nearly £1,000. In explaining an increase of £700 in income tax recoverable under deeds of covenant Dr Glover said that the Medical Insurance Agency which was in the habit of giving the Fund £1,600 a year had come to the conclusion that it might equally well under take a covenant to give that sum annually for seven years and so enable income tax to be recovered on the amount. On the expenditure side 431 maintenance grants had been made amounting to £12,125 and 236 annuities amounting to £6,248. The total distribution including special grants some of them on behalf of other societies and the Christmas gifts was over £22,000. The investments of the Fund stood at purchase price at just over £200,000. One of the most encouraging things that happened last year was the response to Sir Thomas Barlow's Christmas appeal which brought in 1979 and enabled each of the beneficiaries to receive thirty shillings. Another interesting happening was the Davis bequest: it was not possible to carry out the letter of the testator's wishes but the spirit would be met by allocating the invested income for the benefit of those helped by the Fund who were in need of a holiday or treatment in a nursing or convalescent home at the seaside. Dr Glover also presented the financial statement of the Ladies Guild which he said had done more work than ever before in its thirty years history. Mr R. M. Handfield Jones, the honorary secretary, said that for a long time the Fund had been compelled by force of circumstances to limit its grants to the inadequate amounts of £40 for men and £26 for women, but now there were at least twenty-five beneficiaries who were receiving more than £50 a year and several were receiving £100.

The report was adopted on the motion of Dr Glover, seconded by Dr Herbert Spencer. The president, treasurer and honorary secretary were re-elected on the motion of Sir D. Arcey Power, seconded by Professor Grey Turner, and on the motion of Dr C. O. Hawthorne, seconded by Mr Handfield Jones, the members of the committee of management who retire by rotation, were re-elected,

together with Dr N. G. Horner, Dr Egbert Morland, Mr C. P. G. Wakley, and Dr Henry Robinson who was nominated by the Medical Insurance Agency. Dr Hawthorne said that the three editors had the opportunity of speaking week by week to the whole of the medical profession of the country and had frequently used the opportunity in the interests of medical benevolence. He also welcomed the addition to the committee of Dr Robinson who was chairman of council of Epsom College and chairman of the Charities Committee of the British Medical Association. Sir Thomas Barlow proposed an omnibus vote of thanks to the British Medical Association and its Charities Committee, the Medical Insurance Agency, the Medical Sicknes's Annuity and Life Assurance Society, the Ladies Guild and the medical and law journals. He said that the Fund had very good friends. He too welcomed the editors of the medical journals, saying that their presence on the committee would help to identify the work with the profession generally throughout the country. It was stated that it was the intention of the committee instead of issuing a formal report to send a personal letter to all the subscribers and donors explaining again the objects of the Fund and describing the work.

## New Beneficiaries

At a recent meeting of the committee nineteen annuitants were elected, the total amount voted being £355. In addition forty-five beneficiaries (eight new applicants) were awarded grants amounting to £1,120. The following are particulars of three cases.

Widow, aged 69, of MRCS, LRCP, who died in January. Under the will the property and personal effects were left to the widow but the estate consisted only of the house now occupied by a 19-40 hp car and the four hold furniture. After the sale of the house etc. and after out standing debts had been paid it was expected that the capital remaining would not exceed £300. The widow had received no money since her husband's death. The Fund sent an immediate gift of £5 and has voted a further £56 for this year.

Widow, aged 83, of LRCP and S, who died in 1915. The widow is living with her two sisters. One sister is a skilled nurse, looks after the widow and her other sister who is also an invalid. The doctor in attendance reported that the widow was suffering from arthritis and was completely crippled and emphasized the need for the widow to have a permanent attendant but her financial position would not allow of this. The Fund voted £26.

Doctor, aged 65, wife aged 53. The husband is suffering from progressive muscular atrophy. The Fund voted £80 per annum to him and £26 per annum to his wife. The nursing firm for which he worked as a surgeon is contributing £20 per annum.

New annual subscribers are urgently needed by the Fund. Cheques may be sent to the Honorary Treasurer, Royal Medical Benevolent Fund, 11 Chandos Street, Cavendish Square, London W1.

In December 1937 the French Minister of Labour established in Paris an institute for the study and prevention of occupational diseases. This institute the first of its kind in France includes not only a modern well-equipped examination room but also a laboratory permitting extensive chemical and toxicological research and a special photographic laboratory. A library offers to its readers literature, bibliographies and all specialized publications in French, English, Dutch, German and Russian as well as the publications of the International Labour Office. A complete catalogue classifies under the various headings all published articles dealing with the subject of occupational pathology and hygiene. The institute directed by Dr G. Hausser includes on its scientific board such well-known French scientists as Prof. J. Balthazard, Tiffeneau, Duvour, Etienne Martin, Fabre, Kohn, Abrest, Laugier, Godard and Mazel. A publication appearing every two months, *Archives des Maladies Professionnelles d'Hygiène et de Toxicologie Industrielles* will include scientific papers and a complete bibliographical section. The address of the Institut d'Etude et de Prévention des Maladies Professionnelles is 6 Rue de la Douane, Paris, 12.

## Reports of Societies

### SPREAD OF STREPTOCOCCAL INFECTION

At a meeting of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health in London on March 25 a discussion was held on the spread of streptococcal infection as ascertained by type determination. Dr J. A. H. BRINCKER was in the chair.

Dr V. D. ALLISON (Ministry of Health Pathological Laboratory) referred to the classification of haemolytic streptococci into groups by Lancefield's precipitation method, the importance of group A in human disease, and the identification within this group by Griffith of some twenty-six serological types using specific agglutinating sera. The multiplicity of types was of real help in tracing the sources and paths of the spread of infection, while group classification was of little value in this connection, as by it one could not free from suspicion subjects who might be harbouring group A streptococci of types other than those causing the outbreak under investigation. The main value of type determination in infections caused by *St. pyogenes* was in (1) the investigation of the source and paths of infection in explosive outbreaks of streptococcal infection, due, for example, to milk, and in outbreaks of puerperal fever in maternity homes and hospitals, and (2) the investigation of the paths of spread of infection in the wards of general and fever hospitals, and of the effects of reinfection and cross-infection as the cause of grave complications. The advantages of type determination had been well exemplified in many outbreaks some of major importance, during the last few years—for example, the Denham, Chelmsford, and Doncaster outbreaks caused by milk infected with *St. pyogenes*, the source of infection being definitely established in each instance. In numerous outbreaks of puerperal fever the identification of the infecting strain had given a clue leading to the discovery of the source of infection.

Quoting from his own experience Dr Allison said that epidemiological investigations of streptococcal infections in multiple-bed scarlet fever wards and in cubicles had proved conclusively certain facts:

- 1 Patients nursed throughout their illness in cubicles or chambers show no change of the serological type of the infecting streptococcus. Segregation of patients in small wards according to the serological type of the infecting streptococcus revealed that if a change of type did occur it was due to the introduction of fresh infection by a member of the ward staff.

- 2 Infection with one serological type of *St. pyogenes* does not necessarily protect a patient against infection with another type.

- 3 The so-called relapse in scarlet fever is due to fresh infection with a streptococcus conveyed by another patient in the ward and differing in serological type from that causing the primary infection.

- 4 In multiple-bed wards for scarlet fever 50 to 70 per cent of the patients become reinfected with one or more fresh types of *St. pyogenes* during their stay in hospital.

- 5 Such reinfections may be latent or manifest.

- 6 Complications in scarlet fever occurring during the third week and subsequently in multiple bed wards are in the great majority of cases caused by reinfecting types of *St. pyogenes*.

Dr Allison quoted experimental proofs of spread of infection by direct and indirect contact and pointed out the importance of infected toys, handkerchiefs, and eating utensils as vehicles of infection. Air-borne infection by droplets was also a well-recognized means of spread, but the part played by dry dust particles, in which *St. pyogenes* could survive for a considerable time, was only beginning to be recognized. Exposure of blood-agar

plates for short periods in scarlet fever wards and examination of the resulting cultures indicated a surprising high degree of air infection with *St. pyogenes*. The types isolated from the air were exactly those found as infecting agents in the patients in the ward. Finally Dr Allison showed that the problem of the spread of streptococcal infection was of equal importance in measles wards and in the wards of general hospitals. In the epidemiological investigation of streptococcal cross infection in a measles ward over a period of seven weeks, *St. pyogenes* was isolated at some time during their stay in hospital from thirty-five out of forty-three patients and in twenty-two cases had resulted from cross infection occurring in the ward, of seventeen cases of otitis media in the series eight were due to cross infection with types of *St. pyogenes* from other patients in the ward.

### Air-borne Infection

Dr R. CRUICKSHANK (L.C.C. Group Laboratory North Western Hospital) spoke on air-borne infection. By this he meant not "droplet" or "spray infection," which had only a very limited spread, but the dissemination of bacteria by the air. Recent epidemiological and bacteriological work suggested that infection—and not only respiratory tract infection—was spread in spite of rigid precautions to prevent transference manually, by fomites, or by carriers. Wells in America had shown that droplets expelled into the air by coughing and sneezing did not always fall immediately to the ground within a few feet of the individual. If the droplets were not more than 0.1 mm in diameter, evaporation rapidly reduced them to so small a compass that they remained suspended in the air like particles of smoke. Larger droplets or other infective material that had settled might also be evaporated and lifted into the air again as dust. The potentiality of these "droplet nuclei," as Wells called them for spreading infection depended, among other factors on their viability and their concentration. Wells found that certain organisms which commonly occurred in the upper respiratory tract—for example, haemolytic streptococci, pneumococci and *C. diphtheriae*—remained viable in the atmosphere for two days, whereas intestinal bacteria such as *Bact. coli* and *Bact. typhosum* died off within eight hours.

Dr Cruickshank went on to give examples from his own experience of the air-borne spread of streptococcal infection. On one occasion it was found that eight cases of burns in the same ward were infected with the same type of *St. pyogenes*, that the dust and atmosphere of the ward contained numerous haemolytic streptococci, and that a strain isolated from the dust was of the same serological type as that obtained on culture from an infected burn. Great care was taken to prevent manual spread from case to case, and throat carriers among the nursing staff were not common. The second example was that of a small outbreak of puerperal sepsis in which throat carriers and direct transference could be almost certainly excluded, again the epidemic type of *St. pyogenes* was found in the atmosphere of the ward. The occurrence of streptococcal infections (tonsillitis, otitis media, and vaginitis) in a diphtheria ward of young children furnished the third example. In addition to the clinical infections most of the children had haemolytic streptococci in the nose or throat, more particularly in the nose, whereas there were no carriers among the nursing staff. Haemolytic streptococci of the same infecting types were present on plates exposed in the ward and were most numerous where the infected cases were occurring (although the plates were beyond the reach of "droplets") and after the dust of the ward had been stirred up by sweeping and dusting. In conclusion Dr Cruickshank suggested that the nursing staff should not be blamed too readily for the spread of infection, that too much dependence should not be placed on isolation, and that wet dusting should be the routine practice in infected wards.

## General Discussion

Dr R. A. O'BRIEN thought that some of the findings mentioned by the previous two speakers might be open to criticism if they were based on the examination of a single swab from the patient on admission. Mr J. B. LAYTON commented on the tendency to remove otitis cases from earlet fever wards in order that they might be isolated and observed that it was not the otitis case which required isolation but the pre-otitis cases. Dr I. GIBSBY said that however desirable the practice of swabbing and typing of streptococci might be from a scientific point of view, information thus obtained might be misinterpreted in a court of law if an action were brought against a local authority in consequence of cross-infection. With regard to cubicle and chamber nursing he thought it should be remembered that a policy which was practicable in large infectious diseases hospitals might be quite impracticable in the case of the vast majority of small isolation hospitals in this country. Some attempt might be made in these small hospitals to reduce the incidence of so-called relapses in scarlet fever by avoiding any overcrowding of the wards and by grouping cases in such a way that convalescents without complications were not brought into contact with newly admitted acute cases. Dr A. TOLPINE suggested that there was a tendency to attribute the occurrence of puerperal sepsis in a case to a nurse or midwife who happened to harbour a haemolytic streptococcus in her throat or nose without excluding other more likely causes, the *post hoc ergo propter hoc* theory if adopted without full investigation could lead to entirely wrong conclusions.

Dr E. H. R. HARRIES referred to C. V. Chapin's classical *Sources and Modes of Infection* (1910). Chapin discounted the importance of air-borne infection and stressed the part played by droplet spray and by utensils and the hands of attendants. It was at one time believed that by aerial convection the virus of small pox might be transmitted to the unvaccinated over distances such as a quarter of a mile. If dry sweeping was permitted in wards then clouds of dust were inevitable. Damp-sweeping or better still the use of vacuum cleaners was an essential part of the technique of bed isolation. Nobody would intentionally admit patients in the early stage of chicken pox or measles to a bed isolation ward. The infectious conditions most safely managed in these wards without spread were those due to the haemolytic streptococcus. Patients suffering from scarlet fever, erysipelas or puerperal sepsis had in his own experience been nursed at the same time in the same ward under bed isolation conditions without spread of infection to other patients. Nevertheless other factors remaining unaltered it was possible so to increase the load of streptococcal infections in the ward that the system broke down and cross infection occurred. Dr HARRIES stressed the importance of Sheldon Dudley's conception of the "velocities of infection".

Dr SLEIGH, medical officer of health Chatham (late medical officer of health Chelmsford) discussed the Chelmsford outbreak mentioned by Dr Allison. A curious feature of the outbreak was that of thirty-three cases of scarlet fever with onset in the fortnight previous to the milkman infecting the milk, twenty-eight received their milk from the infected source. They were late notifications and so were not typed but this suggested that the milk had been infected earlier than the milkman was infected from his own milk and that the passage through the human host had raised markedly the virulence of the strain leading to the explosive outbreak. Typing had been continued since the outbreak with the assistance of Dr Camps and it was found that in a comparatively small district there were seldom more than three or four types at any one time. All cases showing secondary rises of temperature were re-typed and always showed a different type from that obtained on admission. Recently all his cases were kept in bed till they were fit for discharge. This had lowered considerably the amount of cross infection. Typing also helped in separating out true return cases. A case had been admitted as a probable case of mastoiditis due to Type 6 streptococci. The condition cleared up and he was discharged. Within thirty-six hours he had to be readmitted almost moribund and died within twenty-four

hours of streptococcal meningitis. On typing the pus from the brain it was found to show streptococci of Type 1. There were no other Type 1 cases in the hospital at that time. In regard to swabbing midwives' throats he thought that unless the streptococci found could be typed it was unwise to take swabs at all.

Dr J. MCGARRITY stressed the value of fresh air and bed isolation in ordinary wards and deprecated overcrowding. In Birmingham there were three bed isolation wards where all sorts of doubtful cases were isolated. In these wards cross infection had not been seen at all during recent years. The technique of bed isolation was most carefully carried out and the windows were wide open all the time both night and day even in the winter. The temperature of the ward did not matter, the patients could easily be kept warm with the help of extra blankets and hot water bottles. Dr E. C. BESS (Leeds) speaking of the immunity of Dick-negative reactors to streptococcal infections said that a fall in the relapse rate of earlet fever to less than 1 per cent followed artificial immunization by earlet fever toxin of those children who remained Dick-positive in the second week of the disease. He also mentioned the frequent occurrence of streptococcal tonsillitis in fever nurses during the first four or six weeks of hospital service. As their immunity to streptococcal infection increased either naturally from exposure to infection or as a result of artificial immunization the incidence of streptococcal tonsillitis showed a sharp fall. Dr M. MITCHELL conceded the possibility of aerial contamination by suspended infectious particles but thought that if it occurred it was in most instances the result of droplet spray. Infection in the air or dust became diluted rapidly as the result of drying, the action of sunlight and the movement of air in a well-ventilated ward. In consequence the mass of infection was usually insufficient to initiate an attack of the disease. Direct droplet infection was still the most important mode of transmission of infectious diseases. In investigating the contamination of the atmosphere with suspended particles he suggested as a possible alternative to the elaborate air centrifuge a blood agar plate moving slowly in a vertical direction through the air. An adjacent stationary plate could provide evidence of infection from falling particles. In this way a comparison between floating and falling particles could be obtained. He believed that Dick-negative subjects were on the whole more resistant to haemolytic streptococcal infections than Dick-positive ones. An individual in acquiring immunity to the antigens of the toxin must also have had an opportunity of acquiring some immunity to the antigens of the organism itself such as those responsible for its invasive properties. Although the Dick test was no measure of this bacterial immunity a negative result indicated a previous acquaintance with the organism. Differences in the behaviour of the same type of streptococcus gaining access to the body through different portals of entry was attributable, he thought, to differences in local immunity.

## SILICEOUS DUSTS

At a meeting of the Society of Public Analysts and Other Analytical Chemists held at Burlington House on March 6, Dr H. E. COX presented a paper on the chemistry and analysis of henna. He described the constituents of henna leaf and pointed out that contrary to some earlier literature henna did not contain tannin. The constituent to which its dyeing properties were due was 2-hydroxy-1,4-naphthoquinone. This substance alone or in henna powder could be very satisfactorily determined by means of a volumetric method and apparatus described. The dyeing of hair with the hydroxynaphthoquinone depended on the pH value of the liquid. It required an acid reaction and no satisfactory dyeing could be obtained in neutral or alkaline solutions. This was probably why curious defects or colours sometimes appeared in hair dyed with henna.

Dr JANET W. MATTHEWS gave an account of work carried out in collaboration with Professor H. V. A.

Briscoe P F Holt, and P M Sanderson, the main object of which was to investigate the characters of dusts liable to produce silicosis. Two methods devised for collecting dusts from air in mines and factories, without contact with moisture, were described, in one the air was filtered by suction through a layer of salicylic acid crystals which were subsequently removed by solution in absolute alcohol, and in the other the air was passed through a long chamber (labyrinth) divided by baffles into numerous compartments in which fractional deposition took place. Micro-chemical methods employed in analysing the dusts were briefly described. It was found that siliceous materials were much more hygroscopic in the form of fine dust than in the macro-form and that in the former condition an appreciable quantity of their silica becomes soluble in water. Dusts of calcined flint and asbestos, for example, which were dangerous in respect of silicosis, yielded 12 mg and 30 mg of silica per gramme to 100 ml of water, while cement and sillimanite dusts, which were regarded as innocuous in respect of silicosis, yielded only about 1 mg. The effect of addition of other materials to the siliceous dusts was investigated, and it was found that admixture with an equal proportion of lime greatly reduced the quantity of silica dissolved by water.

### CHRONIC CERVICITIS

At a meeting of the Edinburgh Obstetrical Society on January 12, with the president, Professor JAMES HENDRY in the chair, Dr G DOUGLAS MATTHEW read a paper on the treatment of chronic cervicitis.

Dr Matthew said that some degree of cervical laceration was a common accompaniment of labour, whether spontaneous or instrumental, and this predisposed to cervical infection. Cervicitis in its chronic form was seen characteristically in the multiparous patient with a history dating from a previous confinement. While the majority of cases arose in this way, others followed abortion, instrumental trauma, or direct gonococcal infection. Cervicitis led to much suffering, discomfort, and ill-health, and the outstanding symptoms were pain, discharge, and menstrual irregularity. In some cases urinary symptoms might result from bladder irritation, or involvement by actual infection, while in others the cervix might act as a focus of infection in co-existent systemic disease. There was a definite connexion between chronic infection and carcinoma of the cervix. He believed that some sort of classification of cases was of assistance in the selection of suitable treatment for the individual. He suggested division into the following four groups: superficial cervicitis, endocervicitis with erosion, endocervicitis, and diffuse cervicitis.

The aim of treatment was to eradicate all infection and repair laceration and eversion. The final result should be a smooth supple cervix with a patent canal. Treatment might be conservative, by douching by the local application of antiseptics or caustics, or by ionization, thermal, using the methods of cauterization, electrical coagulation, or diathermy excision, radiotherapeutic, or surgical. He had had the opportunity of using many of these methods in the treatment of patients under the care of Professor Johnstone in the wards of the Royal Infirmary during the past two years. From the results obtained and from a consideration of other methods he had arrived at certain conclusions as to the best form of therapy to be used in each of the four types of cervicitis which he had described. In superficial cervicitis he recommended superficial electrical coagulation without dilatation of the cervix. This could be done in the out-patient department. In cases of endocervicitis with erosion he advocated excision of the affected tissues by diathermy after full dilatation of the cervix. This treatment should be carried out under anaesthesia with the patient in hospital. Bourne's zinc-chloride method might be the ideal treatment for cases of uncomplicated endocervicitis

and diffuse cervicitis was best treated by surgical excision and repair of the cervix, or by amputation in older patients where pregnancy was unlikely.

Dr Matthew concluded by referring to the treatment of cases during the post-natal period, and mentioned results which had been obtained at the Royal Maternity Hospital with electrocoagulation six to eight weeks after delivery. He believed that as this post-natal treatment became more universally adopted the number of patients attending gynaecological out-patient clinics with symptoms of chronic cervicitis would gradually diminish.

At the same meeting Mr HUGH MILLER (Inverness) reported in detail a case of unruptured tubal pregnancy continuing to full term.

### BUNDLE BRANCH BLOCK

A meeting of the section of medicine of the Royal Academy of Medicine in Ireland was held on March 14, with the president, Dr E T FREEMAN, in the chair.

Professor HENRY MOORE, with Drs E KELVIN, W R O FARRELL, and M A MORIARTY made a communication on bundle branch block. Of 2,080 patients examined electrocardiographically thirty-seven showed bundle branch block, an incidence of 1.77 per cent, and eight an indeterminate form of intraventricular conduction defect, the QRS wave being more than 0.12 second in duration. Thirty-five cases gave the common curve of bundle branch block, two the uncommon type of curve. The heaviest incidence was in the sixth decade, and 62 per cent were males. The aetiological factor was apparently vascular hypertension in twenty of the thirty-seven cases, and disease of the coronary arteries without hypertension in five. It was possible to trace thirty-six of the patients, 60 per cent were dead, the average duration of life since the diagnosis was made being 20.4 months, but four patients had lived for more than six years. The presence of intraventricular block was suspected on clinical grounds in twenty-one out of twenty-six cases, such a block was present but clinically unsuspected in five cases. The diagnosis could only be made with certainty, however, by the electrocardiograph.

### Findings at Necropsy

Four cases came to necropsy, the hearts were carefully studied in serial sections, the whole conducting system being followed down to the finer ramifications of the bundle branches in order to discover the interrupting lesion and so to obtain evidence as to whether the new or old nomenclature for the electrocardiographic diagnosis of bundle branch block was correct. Using the new electrocardiographic nomenclature Case 1 had right bundle branch block, Case 2 had left bundle branch block, Case 3 originally showed a left bundle branch block but later the curve became indeterminate in character. Case 4 showed an indeterminate form of curve throughout. In Case 1 a fatty fibrotic lesion interrupted the right bundle branch, in Case 2 a fibrotic lesion had destroyed the left branch. In Case 3, in addition to some congestion of the trunk with, however, apparently healthy fibres an old fibrotic lesion almost completely destroyed the left branch and a lesion of more recent origin in the congestive and to a slight degree fibrotic) caused interruption of a minority of the right bundle branch. The fourth heart (indeterminate form of intraventricular conduction defect) showed no lesion interrupting the conducting tissues down to the finer ramifications of the bundle branch subdivisions but there was a rounded infiltration of about 2 mm in circumference at the apex of the papillary muscle in the right ventricle and was a small old infarct at the apex of the left ventricle. On the whole the results suggested that the new nomenclature was correct. The pathology of the main coronary and coronary arteries was also studied and described.

About 220 000 sections were cut on the four hearts. The anatomical and pathological part of the work was carried out under a grant made by the Medical Research Council of Ireland.

### General Discussion

The president Dr L. J. FREEMAN said that this was the first account which had been presented to the Academy of any work that had been done with monetary help from the Research Council. Dr P. O'FARRELL said that he had seen eleven cases of bundle branch block ill in miles. Ten were of the common type, one of the rare type. Of these patients six had died within two years—three of them died suddenly—three were alive and two he had not been able to trace. It was possible that bundle branch block might be in expression of coronary disease.

Dr W. J. E. JESSOP and Dr ALAN THOMSON also took part in the discussion to which Professor MOORE replied.

At the same meeting Dr C. J. McSWINEY showed a new and improved model of the Briggs-Paul pulsator.

## Local News

### FRANCE

[FROM OUR OWN CORRESPONDENT IN PARIS]

#### The Medical Examination of all Motor Drivers

Hitherto in France a special medical examination has been required only of the drivers of motor lorries, omnibuses and other heavy motor vehicles. The extension of this privilege or imposition of it at what you like to the drivers of all motor vehicles has recently been debated with much keenness at meetings of the Academy of Medicine which has finally decided in favour of it in spite of the misgivings voiced by several speakers. The resolution adopted on March 8 says in effect that such a medical examination would be useful for every driver and necessary in the interests of all motorists. It concludes with the proposal that the Minister of Public Works should appoint a commission to examine this problem. The critics of this measure within the Academy dwelt on the difficulties which would be encountered when a limited number of medical examiners would be called on to deal with an unlimited number running into millions of candidates for medical certificates. It was also pointed out that motor accidents are more often due to flaws in a man's character than to flaws in his physique and that one can not expect the ordinary medical examiner to be gifted with such transcendent psychological insight that he can spot the road hog in advance. One speaker quoted statistics supposed to show that only 0.74 per cent of road accidents had been traced to the faulty physique of the driver. On the other hand there must be many physically ailing motorists including elderly country doctors whose earnings would be seriously threatened by the proposed measure although the likelihood of such drivers causing a serious accident would be very small indeed. What was perhaps the most effective answer to all these inhibitory considerations was the question put by one speaker: Is there a single one of our colleagues who would consent to be driven from Paris to Nice by an epileptic chauffeur? It is remarkable how such a pertinent question can crystallize opinion during a debate conducted with so much ability on both sides that many a listener must have felt that both were in the right or very nearly so.

#### The late Dr Rumond Sibouraud

Though many obituary notices fail to carry conviction because of the well known and on the whole laudible inclination of the writer to give his subject the benefit of the doubt one cannot help being charmed and im-

pressed by the volume and quality of the tributes paid by his friends to the late Dr Sibouraud. He is a remarkable illustration of the proverb imputed to a certain biblical while that you cannot keep a good man down. From the very outset of his medical career Sibouraud was recognized as a coming man. Then a rude check awaited him, a thesis which he had prepared on the subject of ringworm and which represented four years' research was rejected by his examiners in favour of another thesis whose comparative mediocrity was obvious. This judgment a mere incident for the examiners made Sibouraud decide once and for all not to seek promotion by the usual paths but by the intrinsic merit of his own researches. For some time this decision cut him off from the laboratory and hospital appointments that normally go to those who best succeed in pleasing their examiners. But with the support of Roux and others Sibouraud was enabled to pursue his studies in a bacteriologically minded dermatologist and in due course the importance of his work was universally recognized that the hospital appointment he had refused to seek sought him and he was installed at the Saint Louis Hospital where for some thirty years he was the presiding genius to whom the whole world of dermatology came to pay homage. But with all his success he remained the kindly genial modest helpful man at the service of all who sought his advice. The motto up to which Sibouraud lived throughout nearly the whole of his scientific career was: When you are someone you need not be something.

#### Insurance against Professional Risks by *Sou Médical*

*Sou Médical* is a co-operative enterprise all of the profits of which go to swell a reserve guarantee fund. For an annual subscription of 100 francs each its members are insured against all the risks entailed by the practice of medicine. The lively appreciation of these risks by the medical profession is shown by the fact that in only two years the membership of this body has risen from 7 019 to more than 8 000. In 1937 it dealt with 461 affairs, 109 of which concerned disputed doctors' bills. Third party actions accounted for twenty-two cases, medical care for twenty occupational accidents for fifty-eight, conflicts with the tax authorities for seventy-five and misunderstandings between colleagues for twelve. There were eight cases of slander and four penal cases. Only about 10 per cent of all the cases dealt with in 1937 would have been taken up by an ordinary insurance society confining its liabilities only to professional responsibilities. *Sou Médical* is linked up with the weekly journal *Concours Médical* the annual subscription to which is 70 francs. Thus for a total of 170 francs every French doctor who wants to can enjoy a first class medical journal and insurance against the almost countless risks of legal troubles in this highly contentious age.

#### Retirement of Professor Emile Sergent

When a medal was presented to Professor Sergent recently on the occasion of his retirement several among his most distinguished colleagues recalled various incidents in his career. Professor Roger went back some thirty-seven years and called to mind his first meeting with Professor Sergent when in 1901 they had sat opposite each other at an examination table. A fellow examinee whispered on this occasion to Professor Roger: Look at his head! He is going to be Potain's successor! This remarkable prognostication came true and for many years Professor Sergent drew crowded audiences at the *Charité* where Potain had taught. Professor Sergent's gifts as a teacher were so conspicuous that in 1921 a unanimous vote of the council of the Faculty of Medicine endowed him with a new chair as professor of clinical propeaedeutics at the *Charité*. He was not only a great teacher however he was also a brilliant research worker who has contributed much to our knowledge of endocrinology, the diseases of the respiratory system and tuberculosis of this system and of the bile passages.

## Correspondence

### Classification of Adventitious Sounds

SIR—I have been much interested in the correspondence on this subject, and especially by Dr Hutchison's letter in which he pleads for simplification. Personally I always taught my students the original classification of Laennec with as exact an English translation as possible. He introduced the word *râle* which he derived from the 'death-rattle', but he explained that he would take a rather wider application of the word than the accepted one.

Je designeraï sous ce nom tous les bruits contre nature que le passage de l'air pendant l'acte respiratoire peut produire soit en traversant des liquides qui se trouvent dans les bronches ou dans le tissu pulmonaire soit à raison d'un rétrécissement partiel des conduits aériens.

There is no doubt that he used the word *râle* in the widest possible sense that attaches to the English word rattle. Laennec goes on to distinguish five principal kinds of *râle*—as follows:

- 1 Le râle humide ou crépitation
- 2 Le râle muqueux ou gargouillement
- 3 Le râle sec sonore ou ronflement
- 4 Le râle sibilant sec ou sifflement
- 5 Le râle crépitant sec à grosses bulles ou craquement

The two English translators, Herbert (in 1846) and Forbes in his fourth edition of 1834 used the following English equivalents:

Forbes	Herbert
1 Moist crepitous rhonchus or <i>crepitation</i>	Moist crepitant râle or <i>crepitation</i>
2 Mucous rhonchus or <i>gurgling</i>	Mucous or gurgling râle
3 Dry sonorous rhonchus or <i>snoring</i>	Dry sonorous râle or <i>snoring</i>
4 Dry sibilous rhonchus or <i>whistling</i>	Dry sibilant râle or <i>whistling</i>
5 Dry crepitous rhonchus, with large bubbles or <i>crackling</i>	Dry crepitant râle with large bubbles or <i>crackling</i>

These three lists will show how much confusion Dr Forbes caused when he introduced the word 'rhonchus,' saying it was employed by Laennec, but I cannot find that Laennec used it as a complete equivalent of *râle*. In the table alphabetique to the second edition of Laennec's *Traité de l'Auscultation Médiate* (1826) there is the entry RHONCHUS RONFLEMENT VOI RÂLE, but this implies that *rhonchus* is identical with *ronflement* or snoring. Unfortunately Forbes's translation met with wide acceptance and his substitution of *rhonchus* for *râle* has served to puzzle every medical student from that day to this.

A reversion to Laennec's original classification is perhaps the best simplification, provided that the word *râle* is frankly translated by rattle. With that substitution Herbert's version of the classification will be intelligible. Whether Laennec's division of rattles into dry and moist is justifiable must remain debatable.

It has always seemed to me that whilst one may accurately describe sounds as gurgling whistling snoring and crackling to call them wet and dry involves more guesswork than is acoustically or musically permissible. I am not sure whether *craquement* is accurately rendered by crackling; the word used by both Forbes and Herbert. Laennec explains that it is the pathognomonic sign of pulmonary emphysema is only heard during inspiration and resembles the sensation experienced when one presses the stethoscope over a part affected by subcutaneous emphysema—so perhaps crackling is the right word.

There is really no difficulty in finding English equivalents for Laennec's five sorts of rattles with the exception of his first *râle humide ou crépitation*. The word 'crepitation' is not in common English use. Laennec says the sound is like that caused by making salt crackle by warming it slightly in a basin or by blowing up a dry bladder. He explains the sound as caused by the air vesicles containing a liquid almost as thin as water which does not prevent the air penetrating them. The bubbles which form it appear extremely small. This is the crepitation heard in the early stages of pneumonia which disappears during complete consolidation of the lung and reappears (as Laennec described) when resolution occurs. "Crepitation" thus described and defined seems to be a word which we must allow to be adopted into English. With these original explanations which Laennec used we shall do well, in my opinion, to be content. But if we are compelled to read Laennec in a translation not in the original French, I recommend Herbert's translation, not Forbes's—I am, etc.,

### Ascorbic Acid in Bronchial Asthma

SIR—Dr H B Hunt's article (*Journal* April 2, p 770) concludes by saying that his investigations do not show "ascorbic acid to be of any value in the treatment of bronchial asthma when given in comparatively large doses." There are ample reasons for questioning this statement. Clinically one knows and patients themselves have emphasized the benefit to asthmatics of plenty of fresh fruit. Secondly the adrenals are richer in vitamin C than any other organ in the body. Thirdly, the urinary excretion of ascorbic acid for twenty-four hours was investigated in thirty-two asthmatic patients at Stobhill Hospital. In twenty (60 per cent) it was nil and the average excretion of the remaining twelve patients was only 4.8 mg, the highest being 12 mg (normal 15 to 30 mg). Of course, the series is small and belongs to the hospital class in which the excretion of ascorbic acid is likely to be low but surely it is significant that in all the patients the figure was so far below normal sometimes even after eating fruit.

The mode of action of ascorbic acid is admittedly obscure as regards asthma it is probably indirect but not the less potent. It has some relation to vascular spasm. The last two cases of Meniere's disease that I saw promptly got well on taking abundant fruit. The one of one was examined and contained no ascorbic acid. Meniere's disease is the aural analogue of migraine though unlike migraine, it does not often consist in asthma—I am, etc.,

Asthma Clinic Stobhill Hospital,

JAMES ADAM

### After-effects of Modern Treatment of Carcinoma

SIR—The original account by Mr Percy Funnell which led to this correspondence served to show in his own experience that the results of radiotherapeutic treatment like those of other forms of treatment can be stated simply as success or failure according to survival or death of the individual treated. By his case history he demonstrated that the elimination of cancer from certain situations by radiotherapeutic treatment can be associated with such a degree of persistent partial survival may scarcely be desirable. Surgery is although successful in the sense that the disease is

radical may also demand a heavy price in disfigurement from the survivor. Few radiotherapists of experience would seek to deny that considerable room for improvement exists both in technique and in the assessment of cases in their comparatively young branch of medical science.

Some of those whose letters followed Mr Furnivall's have unfortunately expressed exaggerated likes or dislikes for radiotherapy. Either of these attitudes can serve only to retard that co-operation between surgeon and radiotherapist which their respective limitations and the gravity of the subject demand. Dr Douglas Webster (March 26 p 699) for example undoubtedly overstates the case for radiotherapy while Mr W S Dickie (April 2 p 757) verges on the intemperate in his criticism from the supposed surgical point of view. If all Mr Dickie's cases were treated by recognized experts and all had necrosis of soft and bony tissue then something was wrong with his recognition either of necrosis or of experts. From the tone of Mr Furnivall's note it is evident that he only sought to state facts within the range of his own intimate knowledge and had no intention of disparaging radiotherapy or of encouraging others to do so. The pursuit of this branch of treatment to a high standard is difficult from many standpoints—practical, economic and administrative—and the number of well qualified men in training in this country at the moment is inadequate. The painful aftermath of the elimination of disease in Mr Furnivall's case may possibly serve as a stimulus to the establishment of the team work which is the chief promise of future developments in the attack upon cancer.—I am etc

Edinburgh April 4

J J M SRAW

SIR—Mr W S Dickie's letter (April 2 p 757) scarcely does justice to modern radium therapy. I think everybody must feel grateful to Mr Percy Furnivall (February 26 p 450) for so generously giving the results of his own personal and rather painful experience. But looked at in the light of after events there can be little doubt that he received an overdose. Such warnings as that given by Mr Furnivall and in the letter from Mr Dickie serve to emphasize the fact that in dealing with radium as a substitute for surgery we are making use of a powerful weapon, capable of doing harm as well as good and in dealing with large malignant growths only safely made use of by team work. Such a team should be composed of a surgeon, with practical experience not only of operating in the area involved but of the effect of the application of radium assisted by a pathologist and with the dosage controlled by an expert physicist who may or may not be styled a radium officer.

One important principle I think is now being established—that it is unwise to vary the types of irradiation in one and the same case, or, in other words, Do not mix your methods. The worst results I have seen were in two cases in which necrosis of the larynx took place and in one in which the face necrosed—all were treated first of all with radium needles and subsequently by heavy doses of deep x rays. Assuming that the position of the growth and the degree of malignancy as shown by the microscope, remain constant, there is still a considerable variation in the soil in which it grows. It is probable that the surrounding parts offer a resistance to invasion which differs in the individual. Further when the soil has been damaged by years of absorption of alcohol or has been affected by syphilis or even impoverished in its vascular supply by arteriosclerosis it easily undergoes necrosis. Each case

should be carefully judged on its merits at a consultation between the surgeon and the radium officer when the size and distribution of the growth will be estimated as will the character of the soil in which it is found and the proximity to bone. Experience has shown that some bones are much more prone to radium necrosis than others and it is my own practice in dealing with the fauces whenever the growth approaches the ascending ramus of the jaw to remove it and attack the growth from the outside. I think this simple procedure would have saved a great deal of the distress and suffering to which Mr Dickie refers in his letter—I am etc

Birmingham April 8

MUSGRAVE WOODMAN

## Causation of Cancer

SIR—In the *British Medical Journal* of February 24 1934 (p 352) there appeared a letter of mine on cancer research in which I suggested that the key to the prevention of cancer lay in the reinstatement by simple means of man's natural resistance to the development of the disease. It seems to me that what we know about this disease as it occurs in man shows that the search for a so called cancer cure is a futile one and only tends to raise hopes for the future which can never be realized. In connection with the question of cancer prevention it is necessary clearly to visualize the fundamental difference between cancer genesis and cancer growth. We know now both from clinical and experimental evidence that man and animals possess a natural resistance to cancer genesis varying greatly in different individuals. As a general rule the younger the individual the greater is the natural resistance to cancer genesis and the more rapid the actual growth of the cancer. It is obvious that cancer genesis and cancer growth do not run on parallel lines and consequently it can be readily understood that certain agents which have no effect upon the established disease may nevertheless influence the development of the morbid process.

I think that with our present knowledge of physiology it is not beyond the wit of man to visualize the mechanism of the natural resistance to cancer genesis and further more to conceive of simple means which will assist this mechanism to function at its inherent optimal potency. In recent years it has been demonstrated that various agents—chemical, actinic and animate—possess carcinogenic properties. I believe that certain chemical compounds contained in these substances or produced by their action on the body enter the system and act by diminishing the natural resistance to cancer genesis and that the tumour site is determined by local irritation. In this connexion it is suggestive that a chemical compound may have a markedly carcinogenic action and yet may produce little or even no local irritation. I think that in the conception of cancer as a preventable disease lies our real hope for its future control.—I am etc

W MITCHELL STEVENS

## To Nail or Not to Nail Abduction Fractures?

SIR—In the *Journal* of April 9 (p 773) Mr H A Brittain disagrees with my view and Bohler's (who thought it first) that abduction fractures should not be disimpacted and nailed but should be allowed to join spontaneously in the usual slight valgus deformity. I am certainly an advocate of nailing but not a blind advocate. I restrict the operation to those adducted subcapital and

transcervical fractures which are notoriously reluctant to unite by any other means. I do not, however, operate upon patients previously bed-ridden or upon those with a short expectation of life, still less as a cure for pneumonia.

The three-flanged nail has its disadvantages. Though Smith-Petersen's nails increase the chances of union, they slow it down considerably and make it difficult to decide when it has occurred. They break completely across in 8 per cent of cases and, in addition, pieces chip off in about half this proportion. Nail erosion is so common that nobody mentions it. I say nothing of osteo arthritis and aseptic necrosis because these may occur without any operation, but there are occasions when the risks of leaving a nail or removing it seem almost equal. Surely it is better to get union without using a nail when, as in pertrochanteric, intertrochanteric, and abduction fractures, one can feel confident of doing so? Mr Brittain's claim of 85.7 per cent bony union in all cases lacks the support of dates, but Watson-Jones, at Belfast this year, frankly admitted that his figure of 91 per cent (*British Journal of Surgery* April, 1936) had proved optimistic. If surgeons would be content to wait three years for their end-results they would be on safer ground.

The bad results of nailing are generally the results of bad nailing. This applies to reduction and to x-ray technique as well as to the nailing itself. It is so important to put the nail exactly where it is needed (generally axial in both planes) that I have discarded my director which gave mathematical precision with insufficient stability for one designed and made for me by Mr Raymond Fox, which promises to fulfil both requirements. It may be asked how I can still label myself an advocate of nailing. The answer is (*pace* McMurray) that I believe it to be the best method so far discovered, but I confess that my own results—if I could bring myself to think of them in under three years—would remind me of the little girl who had a little curl right in the middle of her forehead—I am, etc.,

London, W 1, April 4

ERIC I. LLOYD

### Multiple Benign Sarcoid and Tuberculous Ulceration

SIR—I am surprised that the case reported by Dr R. Howitt Wiseman under this heading on March 26 (p. 673) has evoked no discussion. It is a pity that the report was not accompanied by any clinical photographs or illustrations of the histological picture. If Dr Wiseman's diagnosis and the interpretation of his findings is accepted, it must be regarded as solving the difficult problem of Boeck's sarcoid. On the evidence submitted I have great difficulty in accepting either his diagnosis or his interpretation of his findings. There is no mention of the Mantoux reaction or of x-ray investigation of the chest or of bone, all of which is of first importance in discussing the problem of sarcoid. If there is a microscopic picture typical of the benign sarcoid it is not that described in this case, and I think I should not be alone in questioning the value of bacteriological examination of scrapings from the edge of an ulcer to confirm the diagnosis of tuberculosis. It will be interesting to learn the further history of this case beyond the investigation stage, and to know whether the question of mycosis fungoides or allied affections was considered. I should have thought the diagnosis rested between this group and leprosy—I am, etc.,

Leeds, April 2

JOHN T. INGRAM

### "Gonococcus Antitoxin" for Gonorrhoea

SIR—It is with much interest that I have followed in your columns the papers by Dr Anwyl Davies and by Drs Burke, Harkness, Gabe, and King in regard to the treatment of gonorrhoea with antitoxin. The difference in their results is most instructive.

All scientific workers would probably agree that the careful planning of an experiment so that it may at least be reasonably expected to prove or disprove that which it sets out to prove or disprove is the first essential towards obtaining a result of practical value. It would seem that whereas in the work of Drs Burke, Harkness, Gabe, and King the method adopted was carefully thought out and suitably controlled with a particular end in view that of Dr Anwyl-Davies would appear to fall far short of this standard. Moreover, it seems that the former authors carried out their work entirely independently of each other and only afterwards pooled their results—a fact which materially enhances the value of their experiments. In the case of Dr Anwyl-Davies's work it is very difficult to determine what scientific method of approach was adopted or what bearing the results obtained have upon the efficacy or otherwise of the antitoxin in the treatment of gonorrhoea because of the "adjuvant treatment" which was given at the same time. What strikes one very forcibly is that the deductions made by Dr Anwyl Davies as a result of his work appear to be very much at fault.

Let us suppose that he had done his work in the light of the more recent experiments of Dr Burke and his co-workers (and it would seem that it could only be of some value *after* these experiments), one would have expected his deductions to confirm in some degree, and not confound, the findings of these workers. Here are two sets of workers, one using antitoxin together with a recognized modern method for the treatment of gonorrhoea (called "adjuvant") and the other using antitoxin alone. One set of experiments yields good results and the other bad results. The deductions are, of course (1) that the "adjuvant" is most likely responsible for the good results, since it is the only important thing that is not common to all the workers, and as a corollary to this (2) that the antitoxin has no beneficial effect in the treatment of gonorrhoea—as Drs Burke, Harkness, Gabe, and King suggest. Furthermore, in a number of their cases severe local and general reactions were noticed, whereas in Dr Anwyl Davies's work these were by no means such a formidable feature. Again the 'adjuvant' probably explains the discrepancy. The deduction here is that not only is the antitoxin of no benefit, but in a number of cases it would appear to be positively harmful—again as suggested by Dr Burke and his co-workers. Finally, it would be interesting to know whether or not Dr Anwyl Davies used protosil or some allied substance in some or all of his cases 'by way of adjuvant'—I am, etc.,

London W 2, April 10

### Use of Measles Serum in a School

SIR—On January 18, 1938, the spring term began, and on January 20 information was received that the sister of a boy in the school had that day developed measles. The boy was at once removed to the sanatorium, and on the same day showed signs of measles. Consultations held by the head master and medical officers predicted the introduction that there were in the school thirty boys who had

had measles. This small number is due to the fact that there had been an epidemic of measles in the school two years before. Of this number there were five who were — contacts a — standing for dormitory house or term contact. These were at once segregated and it was decided to attempt control of what might prove to be an epidemic by the use of measles serum. While permission was being sought and obtained from the parents of the contacts adult serum was with considerable difficulty obtained largely through the help and interest of Dr E M Darmid, assistant pathologist Salisbury. Each of the contacts was given 10 ccm adult serum. Incidentally the parents of one boy who was not a contact and had not had measles asked for inoculation. After an interval of nine days new cases reported and this continued until a total of sixteen boys came under treatment. Of this number six were boys who had serum. The epidemic was not of a severe type.

The main object of this note is to stress the advantage of using measles serum. The clinical contrast during the course of the disease was most spectacular. The patients who had serum were never ill. The rash was at no time fully developed. Its distribution was very uneven and I found it lasted longer. There was an entire absence of coryza and photophobia. Laryngeal and bronchial symptoms were negligible. The average period of pyrexia was two days. In the case of the un inoculated patients it was five days. There was no complication of any kind in the boys who had serum and it will certainly be commended in any future outbreak. The injection of the serum produced no reaction. The injections were always given in the evening and each boy was instructed to stay in bed next morning; he did not feel quite fit. In no case did he take advantage of this; he got up and did full justice to a good breakfast.

As will be noted from the above remarks there is no evidence of temporary immunity but there is undoubted evidence of attenuation of the disease and absence of complications. With such a strong weapon now added to the equipment of the physician it is hoped there will be in the immediate future provision made for the speedy supply of serum for the needs of the community.

I gladly acknowledge the helpful assistance of Sir Kave Le Fleming in interview and correspondence—I am etc.,

W J GRAY LRCP LRCS

### Unequal Pupils in Unconvicted Prisoners

SIR—As more than once I have had occasion to relieve doctors' worries about unequal pupils occurring not only in their patients but in themselves it seems desirable to comment upon the statement by Dr H K Snell and Dr G A Cormack (*Journal* March 26 p 672) that 'anisocoria associated with changes in the pupillary reaction invariably indicates a definite organic lesion and is often accompanied by other signs of the disease. That it can indicate such a lesion is common knowledge but Adie showed some years ago that dilated and inactive pupils can even be associated with absence of knee jerks and yet be a benign condition. Of course there may be an organic lesion to explain the syndrome but I am not aware that it has been discovered and for the peace of mind of the sufferers the term 'functional' had better be used to describe the phenomenon. For many years I have been making observations upon anisocoria and have come to the conclusion that in ophthalmic practice a common cause is emotional stress. I published in this *Journal* notes

of a case illustrating how such stress could work even at long range (1925 2 1179). Long before that Professor Millus Culpin had told me of the occurrence of unequal pupils in his shell shocked patients.

Dr Snell and Dr Cormack in their article state that none of our cases showed evidence of mental disorder associated with anisocoria. The value of this observation depends upon the definition of mental disorder. It has long been my custom to regard pronounced inequality of the pupils especially when of sudden onset as a sign of an anxiety state, an all too common mental disorder. Is it not significant that in many cases the inequality noted overnight was no longer present at the second examination the following morning? The suggestion that fatigue was the determining factor seems an inadequate explanation without qualification as to the nature of the fatigue. Since the state of mind of most offenders while wondering what fate awaits them must be the most exhausting process they undergo I presume that the authors refer to mental and not physical fatigue. Is not the situation comparable to that of soldiers waiting to go over the top? In the 90 per cent of cases that recovered after a night's rest some adaptation to evil circumstances may be assumed.

To sleep upon it is a well known way of settling conflict and securing peace of mind. But I think that an experienced psychologist would have little difficulty in showing temperamental differences between those who recovered so quickly and those whose nervous system had received a more lasting impression. Direct official questioning about feelings is not likely to get at the truth. Just as in the great war soldiers would not admit fear so may unconvicted prisoners repress emotion. But as is shown by the traditional custom in India of detecting criminals by giving suspects a mouthful of rice and noticing which of them failed to insalivate it the nervous system has its own way of revealing emotional secrets. A case in point may perhaps be quoted.

A man aged 40 came to me on December 10 1928 with a widely dilated right pupil virtually inactive to light and accommodation the left pupil was normal. His sight for distance and reading was unimpaired. The day before he had got a flake into his eye from his brother's wireless battery. He was frightened for a few minutes but the eye soon became comfortable and it was not until he returned to his own home four hours later that he learned from his mother that his eyes looked odd. I asked a colleague sceptical of my views to explain the phenomenon on purely physical lines. He failed and I undertook to explain it from the emotional point of view. As I pointed out in 1925 and again in 1927 grief can cause such a lesion and I began now by asking the patient if his father or mother had just died. He replied 'No but my father lay dying in hospital yesterday morning. And then with great rashness I offered to tell the rest of the story. I said 'You wanted to listen to the morning bulletin about King George's health yesterday and were preparing the wireless set for that purpose. You were very anxious for while you contemplated the King's apparently long struggle for life in spite of the attentions of many eminent physicians you were thinking with a sinking heart how little chance your father had in a small cottage hospital. I should not be surprised to learn that your father had the same disease as the King. The guess was right, even to the last particular. His father had an empyema and was not expected to live through the day actually he recovered. At this point my colleague halted convinced urged. But you maintain that when the dilatation is monocular it is usually on the left side here the right eye is affected. To which I replied 'My experience is limited but if you ask the patient you will find he is left-handed. He has merely changed sides. Again the guess was right. Anisocoria has its uses. The pupil slowly recovered in the next few weeks and a month later was normal.

My patient had other symptoms indicative of a neurotic disposition. He suffered from depression easily disturbed sleep, claustrophobia, fear of the dark, had fever, and nervousness when riding on a bicycle or in a motor car. The vaso-motor disturbances so commonly associated with these symptoms were manifest in his cold, clammy, bluish-red hands. Occasionally even in summer and especially at meal-times his fingers and toes would become white and dead. Several years later when investigating the psychogenesis of pritch-crythema of the face and neck I asked this same patient to come for a further examination. His pupils were then normal, but he had a pale face and very red ears and neck. With the psychological significance of 'getting it in the neck' in my mind, I used a stock inquiry and asked, 'How do you react to anything rather tight, like a scarf or collar round your neck?' He replied 'I awake at night fairly often with a sensation as if someone had a piece of rope round my neck and was gradually tightening it. When it becomes really tight I awake in a great fright and call out. My parents often hear the cry.' He was indeed "getting it in the neck" in his dream life, and I was not surprised when in answer to my next question, he said, 'I never read detective tales—they are not even allowed in the house.' If such a man were ever in the plight of an unconvicted prisoner he would not be amongst those whose pupillary inequality adjusts itself in a single night.

The very word "pupil"—from *pupilla* a ward or minor—arouses curiosity as to why the opening in the iris was thus named, and the literal meaning of belladonna—beautiful lady—shows the strange emotional value attached to larger pupils, even when artificially induced. Can any useful conclusions as regards guilt be drawn from emotionally determined inequality of the pupils? I cannot say as far as conscious guilt goes. A tough lag might not bit an eyelid or dilate a pupil anyhow, it might be different if a conscience-stricken elder of the kirk were suddenly called upon to declare, in a police court, whether he had really been his brother's keeper or not. My patient I feel sure, was a thoroughly worthy citizen, but one equally worthy once said when watching a felon being taken to execution, "There, but for the grace of God"—I am, etc.,

Portsmouth, April 3

### Abuse of Ephedrine

SIR,—In Professor J H Gaddum's interesting article on ephedrine, appearing in the *Journal* of April 2 (p 713), I notice that he states that this drug is 'having rather a vogue for local application to the nose, where it produces vasoconstriction and dries up secretions.'

For many years I have regarded this drug as being one of the most dangerous decorations of the average bathroom shelf. It appears in various forms of gaudy bottle, complete with nasal dropper, and is advised in all forms of nasal congestion. The contents give temporary relief in acute coryzal congestion. Such relief is sought by the patient repeatedly, and secretions are kept dried up. Inflammation of the antrum is the usual end-result. This may certainly be mild and transitory, but frequently is more serious, the degree of damage being to a certain extent proportionate to the number of applications of the contents of the dropper.

I consider that it is the ephedrine content of the oily emulsions which should be banned from the treatment of acute coryza. I speak from the observation of innumerable cases seen in general practice, and I should be interested to hear whether it receives the confirmation of other practitioners—I am, etc.,

### Food Supplies and Defence

SIR,—You kindly published in your issue of May 23 1936 (p 1079), a letter of mine indicating the possibility and urging the necessity for this country of self-sufficiency in essential foods. True there has been some movement in this direction, for which we may be thankful to the Government, but it has been perilously slow, and now, with a situation abroad more menacing to this country than any since 1918 it is manifest there is widespread apprehension of defeat through starvation in the event of war. In my opinion it is unwise to count on assistance from beyond the confines of the British Empire, if not, indeed, from beyond the shores of Britain. Armaments alone are inadequate. However gigantic they may be, panic as to the inadequacy of our food supplies may still be inevitable unless we hasten to assure our home supplies.

I invite a reference to the report of the Committee on Nutrition, issued by the British Medical Association in November, 1933. Page 12 contains "Table II—Daily Requirements of an Adult Male in Calories, Protein, Fat, and Carbohydrates." These are

First class protein	50 grammes
Second class protein	50 "
Fat	100 "
Carbohydrate	500 "

The second-class protein and some of the fat can be supplied by cereals, as the table shows. If only by reason of the certain lack of shipping in the event of war, surely it has been folly not to produce the carbohydrates from the home soil, as that soil can produce all we need. Every million pounds spent on cereal production will obviate the spending of ten times as much on armaments. Page 24 of the B M A report gives "Diet No 3—Adult Ration No Meat or Fish," and it is stated "This diet has been devised to enable those persons who object to eating flesh foods to obtain a diet which is satisfactory as regards its constituents. The first-class protein in this diet is derived from milk and cheese. The cost is approximately the same as that of the preceding diet." As an acre of land when used for dairy farming produces at least twice as much first-class protein and fats as when producing meat it is astonishing that at the present juncture the Government should encourage meat production, especially as, without such encouragement, there would still be ample meat when the land is producing essential foods.

The Government appears to be averse to formulating and enforcing an agricultural policy that will assure us against starvation in war time. I venture to submit this policy must be one that is in normal operation in time of peace, and that assures essential foods with the minimum of labour-cost, thus setting free the maximum number for active service in the event of war. Maybe it is but envisaging this policy from another aspect to say a national policy should aim at the maximum production that can be supported in health on the produce of the home soil. This is the policy of Germany and Italy. It is, indeed, the policy on which the sages of all religions have been agreed. It has no place for our so-called high standard of living, advocates of which are generally also advocates of a restricted population. Britain can support in health double its present population on the produce of its own soil. Had it that population at the present moment we should be living free from all apprehensions of war!—I am, etc.,

London, W 14, April 5

## Chemotherapy of Virus Diseases

SIR—In view of the number of different bacteria which are influenced by prontosil sulphamidamide and allied compounds it is only natural that the effect of the drugs should have been tested on virus infections. Although a number of workers have obtained negative results in virus diseases Rosenthal Woolley and Bauer (1937) claim to have influenced lymphocytic choriomeningitis infections in mice with prontosil rubrum. Employing two strains of the virus of lymphocytic choriomeningitis isolated in this country and employing the same technique as the American workers we have failed entirely to influence this infection in any way with prontosil rubrum. These results are in agreement with those recently published by Rouse (1938) and Levaditi (1938). Yellow fever infections in the monkey and mouse and Rift Valley fever in the mouse have also been unaffected by prontosil and allied drugs. A fuller account of these experiments will be published in due course—We are etc

## Sodium Sulphanilyl Sulphanilate and Canine Distemper

SIR—Since the appearance of the paper by Dochez and Slancetz (*Science* 1938 87 142) in which they reported their observation that sodium sulphanilyl sulphanilate was of value in the prevention and treatment of canine distemper a number of veterinary practitioners have inquired as to the effect of this drug. A considerable number of experiments have been completed in these laboratories and our results are not in parallel with those described in the American publication. In our hands this drug has not influenced the course of infection with the Carre Laidlaw Dunkin distemper virus either in ferrets or in dogs. At present we know of no obvious explanation for this complete discrepancy and we hope at an early date to publish the details of our experiments.

The above drug should not be confused with sulphanilamide which in our preliminary experiments appears to have little or no influence on the course of infection with the distemper virus but does seem to control the secondary infections.

We are in communication with Dr Dochez but in view of the interest which has been aroused by the original paper commented on in the *Journal* of April 9 (p 791) felt that a short note of our results would be of interest—We are etc

## Smoking and Longevity

SIR—In your annotation on this subject in the *Journal* of April 9 (p 791) you appear to be in some doubt as to the existence of an anti tobacco league. May I lighten your darkness by informing you that a National Society of Non Smokers was founded in 1926 with an organ entitled *Clean Air*. The aim of the society is the maintenance of the right of every non smoker to clean air unpolluted by tobacco smoke in which to take his or her food, to travel to do business or to seek entertainment. Further information about this society which numbers over 1 300 members may be obtained from the secretary 20 Essex Street, W.C.2—I am etc

## Obituary

Dr DAVID EDWARD RICHARDS who has died at his residence in Tondur near Bridgend South Wales received his medical education at Anderson College St Mungo's College and the Western Infirmary Glasgow. In 1892 he took the triple Scottish Diploma L.R.C.P. L.R.C.S.E.D. and L.R.F.P.S.Glas. and ten years later proceeded to the Fellowship of the Royal College of Surgeons of Edinburgh. He practised near Bridgend and was surgeon to the cottage hospital there consulting surgeon to the Great Western Railway and medical officer and public vaccinator. He was also a medical officer to the Post Office and the Board of Education as well as to various assurance societies. He joined the British Medical Association in 1901.

Mr EDWARD JOSEPH FOX of Warrington died on March 31 at the age of 65. Born in Warrington in 1873 the son of the late Dr Edward Austin Fox he was at Stonyhurst College from 1885 to 1890 when he went to Owens College Manchester and later to St Bartholomew's Hospital. In 1894 he graduated B.Sc. Lond. with honours in physiology and three years later obtained the diplomas M.R.C.S. L.R.C.P. He proceeded F.R.C.S. Eng. in 1899. He held the posts of house surgeon to Manchester Royal Infirmary Manchester Southern Hospital and Saltord Royal Hospital. Having determined to specialize in diseases of the eye he became clinical assistant to the Royal London Ophthalmic Hospital and subsequently began to practise in Warrington where he was appointed ophthalmic surgeon to the Royal Infirmary. He was a member of the North of England Ophthalmological Society and joined the British Medical Association in 1911.

Dr JAMES GODDING O.B.E. died on March 31 at his residence in Worthing aged 74. He received his medical education at the London Hospital and obtained the diplomas M.R.C.S. L.R.C.P. in 1889. After a period of general practice and having been medical officer for the London District to the Corporation of Trinity House he became in 1896 medical officer to the London and India Docks Joint Committee and medical examiner to the Shipping Federation and various steamship lines. In 1907 he was appointed deputy coroner for the eastern division of the County of London and then joined Gray's Inn being called to the Bar in 1911. In 1898 Dr Godding held the commission of surgeon lieutenant in the 1st Middlesex Regiment which was a volunteer corps recruited from the staffs of the docks companies and H.M. Customs in the Port of London. He subsequently transferred to the combatant corps which eventually became the 17th London Regiment in the Territorial Army. He was in command of this regiment at the outbreak of the last war and was on active service with it in France and Egypt until 1917 when he transferred to the Royal Army Medical Corps and as lieutenant colonel was in charge of No 17 General Hospital E.E.F. He was mentioned four times in despatches. In 1920 he became full time medical officer to the Port of London Authority. He was a member of the B.M.A. Ship Surgeons Subcommittee from 1919 to 1920. On his retirement from the Port of London Authority in 1930 he received a presentation of silver plate and the value of his work was very highly commended. He held the Territorial Decoration.

Dr JAMES W. PUTNAM neurologist who was expert witness for the State at the trial in 1901 of Leon Czolgosz, alias Fred Nieman assassin of President William McKinley died at Buffalo New York on March 23 aged 77.

Dr LOUIS WILLIAM STERN since 1934 professor of psychology at Duke University Durham North Carolina and formerly of Breslau and Hamburg died on March 27 aged 67. He originated the concept of the IQ (Intelligence Quotient) which is so popular in the U.S.A.

## Medical Notes in Parliament

The House of Commons rose for Easter on April 14. It is due to reassemble on April 26, when the Budget will be opened.

The Housing (Agricultural Population) (Scotland) Bill was read a second time by the House of Lords on April 7. On the same day the Lords read the Army and Air Force (Annual) Bill. Lord Strathcona and Mount Royal pointed out that Clause 6 of this Bill abolished an obsolete class of "hospital apprentice" in India.

On April 6 the House of Commons supported a motion brought forward by Mr Roland Robinson advocating the even distribution of holidays through the summer months and calling on the Minister of Education and the Minister of Labour to consult together with a view to eliminating obstacles to this. Sir Henry Morris-Jones, speaking as a medical man who had practised in a seaside resort, said it was pernicious that the holiday season should be concentrated into one month of the year. In the same debate Mr Chuter Ede and other speakers advocated altering the season at which the academic year began at universities and schools. Mr Ernest Brown said the co-operation which was advised between his Department and the Board of Education would be assured. Mr Robinson then withdrew his motion.

On the same day the House nominated six members to join with six Peers in a Joint Select Committee on the Collecting Charities (Regulation) Bill.

When the House of Commons read the Patents, etc (International Conventions) Bill a second time on April 8 Captain Wallace said one clause gave effect to amendment in the international agreement for the prevention of false indications of origin on goods, as revised in 1934. By this change the agreement covered the use of all indications in the nature of publicity capable of deceiving the public as to the origin of the goods and appearing not only on the goods themselves but on signs, advertisements, business letters, or any other commercial communications.

Dr Edith Summerskill took her seat in the House of Commons on April 11 as member for West Fulham, in the room of the late Sir Cyril Cobb. She was introduced by Sir Charles Edwards and Sir Stafford Cripps.

Sir Francis Fremantle has been appointed to the Select Committee of Lords and Commons on the Food and Drugs Bill.

Reference books on medicine and medical jurisprudence have been added to the library of the House of Commons. The lack of these had been remarked by the Parliamentary Medical Committee.

### Infanticide Bill

VISCOUNT DAWSON OF PENN moved on April 7 that the House of Lords resolve itself into a Committee on the Infanticide Bill to which the House had on March 22 unanimously given a second reading. He interpreted that manifestation of opinion as meaning the House felt that if it was once proved in court that a defendant was not responsible for her actions by reason of the state of her mind at the time of the offence the possibility should be removed of that defendant being exposed to a possible charge of murder to a verdict of guilty of murder or as an alternative to guilty but insane. Either of those verdicts denied the principle of the Bill. He had hoped to put this question beyond all doubt by two simple amendments in committee. He had hoped in this Bill to make clear that when a court of assize had satisfied itself that a defendant was irresponsible by reason of the then state of her mind it would be possible to return a verdict of insane at the time therefore not responsible therefore not guilty, a term of verdict in vogue before an Act of 1883. Lord Atkins's committee had unanimously recommended fifteen

years ago that there should be a reversion to the old form of verdict. Lord Dawson said he had consulted his legal friends who favoured an alteration of the law but said it should not be altered for this group of cases only. In many other cases of irresponsibility they would wish to go back to the verdict of insane at the time, therefore not guilty. These legal friends were firmly of opinion that it would be better to bring in a separate Bill, to which they would be favourable. He must bow to this opinion, although he did so with great regret.

The ARCHBISHOP OF CANTERBURY said he shared Lord Dawson's disappointment at finding it was not possible to introduce the suggested amendment in this Bill. It would be well if early legislation were brought in to give effect to the recommendations of Lord Atkins's committee. The EARL OF MUMSTER on behalf of the Government said he would convey to the Home Secretary the views that had been expressed.

The House then went into committee on the Bill and agreed without debate to amendments proposed by Lord Dawson. By these a recently born child is defined to be a child under the age of 12 months, and the circumstances for applying the provisions of the Bill to a mother were defined as being that 'the balance of her mind was disturbed by reason of her not having fully recovered from the effect of giving birth to the child or by reason of the effect of lactation consequent upon the birth of the child'. A further amendment was accepted to provide that the Infanticide Act, 1922 be repealed. The long title of the Bill was amended so that the phrase 'a woman who wilfully causes the death of her child' no longer appears in it.

The report stage was set down for April 12.

### Measles Serum

MR W LEACH asked on April 7 whether disappointing results had followed the recent use of measles serum in London County Council hospitals. He asked for strict investigation of the claims made for the various serums in use in view of recent criticism of a medical officer of health in regard to the employment of measles serum. Sir KINGSTLEY WOOD replied that special reports published by the London County Council on the epidemics of 1931-2 and 1933-4 stated that both convalescent and adult measles serum had proved of great value. The report on the epidemic of 1935-6 had not yet been published, but there was no diminution of confidence on the part of this authority in the value of the serum. There would not appear to be grounds for a special investigation.

*Hospital Appointment in Seychelles*—On April 4 Mr KELLY asked the Secretary of State for the Colonies if he had considered a petition asking that a doctor, not a dentist should be appointed to the Government hospital in the Isle of Seychelles. Mr ORMSBY GORE said that a petition was addressed to him last November protesting against the employment of a Government dentist at the Government hospital in the Seychelles. The petition contained no reference to the appointment of a doctor. He did not see his way to interfere.

*Health Insurance Benefits in Incurable Illness*—On April 6 Mr PARKER asked the Minister of Health whether he proposed to use the national health insurance funds to increase benefits to those disabled by incurable illness. Mr BERNAYS replied that provision was already made under the scheme of national health insurance for persons who were insured under the Acts at the time when they became disabled. Such persons, as soon as they had paid 104 weekly contributions, became entitled to disablement benefit up to the age of 65, and thereafter to an old age pension for the rest of life. Any approved society which had a disposable surplus on valuation might apply part of it to increasing the standard rate of disablement benefit and societies covering a large percentage of the whole insured population had already done so.

*Contributory Hospital Scheme for Government Staff*—Colonel COLVILLE announced on April 6 that a scheme would be made available to all Government staffs at home and abroad.

and ten industrial to make contributions for hospital purposes. The non-industrial staff numbered approximately 70000.

**Tuberculosis Inquiry in Wales**—Mr. B. Evans replied to Mr. J. Griffiths on April 11 and that a committee of which Mr. L. C. Davies was chairman had not yet completed its inquiries into the problem of tuberculosis in Wales. It proposed to hold a further sitting towards the end of this month. The Minister of Health would consider the question of the publication of the report as soon as he received it.

**Health of Abyssinian Refugees**—The number of Ethiopian refugees in Kenya is 6181. In a report prepared at the end of October last by the medical officer in charge of the camp it was stated that as a result of measures taken by the authorities in Kenya a great improvement had taken place in the health of the refugees, especially of the children.

#### News in Brief

During the year ended March 31 1937 thirty-eight pedestrians were killed and 1778 injured in Great Britain while crossing the road at junctions where traffic lights are installed.

The scheme for giving additional nutritive food to expectant and nursing mothers in the p.e.t. area is being followed with the closest attention by the Medical Research Council and by the Minister of Health but in the opinion of the latter be regarded as in the experimental stage. The Minister is not in a position to make any general statement upon the results obtained.

The Government cannot provide special facilities for the Contraceptives Bill during the present session.

Returns received from 1271 local authorities in England and Wales show that during the seven years ending on that date 621,578 houses had been reconditioned under the Housing Acts 1920 and 1926 in the areas of those authorities.

Slum clearance programmes of the local authorities outside London affect some 387,000 houses. Of these about 240,000 have been included in clearance and demolition orders. Up to the end of last year about 150,000 of the houses had been demolished and about 161,000 new dwellings provided for persons so displaced.

## The Services

### AUXILIARY RAMC FUNDS

The annual meeting of the members of the Auxiliary RAMC Funds will be held at 5.15 pm on Friday April 29 at 11 Chandos Street Cavendish Square W. When the annual report and financial statement for the year ended December 31 1937 will be presented and the officers and committee for the current year elected.

### No 4 FIELD AMBULANCE OLD COMRADES ASSOCIATION

Staff Sergeant J. McKEOWN, RAMC, writes from 90 Ashurst Road North Finchley N.12. As organizer of the reunion and dinner of the above unit I am desirous of getting in touch with all the officers who served with the unit during 1914-19. Will any officer who has not heard from me please communicate with me at the above address? I should also be pleased to hear from any medical officer who served with the No 3 or No 9 Field Ambulance or in the Guards Division.

### DEATHS IN THE SERVICES

Major DANIEL MCKELVEY, MC, RAMC, died recently in the Queen Alexandra Military Hospital Millbank London aged 46. He was born on September 5 1891 the elder son of John H. McKelvey of Dunbunraver Gortin Co. Tyrone and

was educated at Edinburgh University. He graduated MB ChB in 1914. He proceeded MD in 1919. He also held at St. Mary's and Guy's Hospitals and took the F.R.C.S. in 1927. After filling the posts of resident physician at Edinburgh Royal Infirmary and at the Dreadnought Hospital Greenwich during the war he began a temporary commission as lieutenant in the Royal Army Medical Corps. On November 1 1914 he became temporary captain took a permanent commission in that rank on May 1 1915 and became major on November 1 1926. He served throughout the war of 1914-18 when he gained the Military Cross and later two bars to the Cross. Also the French Croix de Guerre with palm leaves. He was once taken prisoner but escaped. After the war he served in Egypt Hong Kong and India. He gained the Alexander Memorial Prize and Gold Medal at the Royal Army Medical College in 1921. He is unmarried. He had been a member of the British Medical Association since 1915 and from November 1931 officer and 1933 president of the Hong Kong and China Branch.

## Universities and Colleges

### UNIVERSITY OF OXFORD

The George Herbert Hunt Travelling Scholarship for 1938 has been awarded to W. E. Gibb B.M. of Oriel College.

### UNIVERSITY OF LONDON

#### Recognition of Teachers

The following have been recognized as teachers of the University in the subjects indicated in parenthesis.

University College Dr. Matthew Young (Anaesthetics). St. Thomas's Hospital Medical School Dr. Evan Jones (Medicine).

Westminster Hospital Medical School Mr. E. S. Lee (Surgey).

London (The St. Free Hospital) School of Medicine Dr. F. P. Lee Larder (Medicine).

University College Hospital Medical School Dr. M. W. P. Hudon (Anæsthetics). Dr. A. J. Morland and Dr. E. A. B. Pritenard (Medicine). and Mr. S. G. Suggett (Otolaryngology).

### MB B.S. Examination—Annulment of Regulations

New regulations for internal and external students with come into force in and after the session 1938-9 but up to and including May 1940 internal and external students are permitted to proceed to the MB B.S. degree either under the present regulations or under the revised regulations.

### Presentation Days

The ceremony of presentation for degrees will take place at the Royal Albert Hall on Wednesday May 11 at 2.0 pm and at 7.0 pm the same day the annual service for members of the University will be held at St. Paul's Cathedral when the preacher will be the Right Reverend Mervin Blackie Dean of Rochester. Applicant for tickets should enclose a stamped addressed envelope and state their sex and whether they are teachers in the University (graduates (giving degree) or undergraduate.

### Lectures

A lecture on Comparative Histophysiology of the Vertebrate Nephron will be given by Dr. Pol Gerard professor of histology in the Université Libre de Bruxelles at King's College Strand W.C. on May 1 at 5.30 pm. The lecture will be taken by Dr. F. R. Winton.

Dr. J. W. Trevan will give a course of three lectures on "Variation in the Response of Animals to Drugs" at the Wellcome Institute for Medical Research Euston Road N.W. on May 2<sup>nd</sup> 3<sup>rd</sup> and 25<sup>th</sup> at 5.30 pm. At the first lecture the chair will be taken by Sir Henry Dale F.R.S.

A public lecture on "Some Aspects of Heart Sounds in Normal Pathological Conditions" will be delivered by Dr. E. Braun Menéndez of the Institute of Physiology in the Faculty of Medical Sciences Buenos Aires at University College Gower Street W.C. on Tuesday May 3 at 5 pm.

### UNIVERSITY OF MANCHESTER

On Founder's Day May 18 the honorary degree of Doctor of Science will be conferred on Sir Henry Dale M.D. F.R.S., who was unable to attend to receive it last year.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 2, 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths and of Deaths recorded under each infectious disease, are for (a) The 125 great towns (122 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 15 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)	
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)	(a)	(b)
Cerebrospinal fever	32	6	12	3	—	24	4	7	3	1		
Deaths		1	4				3	1				
Diphtheria	1,388	144	239	76	38	926	119	181	46	33	1,053	157

† After October 1 1937 puerperal fever was made notifiable only in the Administrative County of London

‡ Deaths from puerperal sepsis  
§ Includes primary form in figures for England and Wales (London Administrative County) and Northern Ireland

## EPIDEMIOLOGICAL NOTES

## Diphtheria and Scarlet Fever

The incidence of diphtheria in England and Wales and in London showed a slight fall compared with the previous week. On the other hand slight increases in notifications were recorded in Scotland, Eire, and Northern Ireland. Fewer deaths were reported in the 125 Great Towns including London, and in the sixteen principal towns of Scotland, in Eire deaths rose from 1 to 3, and in Northern Ireland 1 death each week was recorded. There was a slight rise in the notifications of scarlet fever in England and Wales, Scotland, and Eire, and a slight fall in London and in Northern Ireland.

## Pneumonia

There were slightly fewer cases of pneumonia (influenza and primary torrid) in England and Wales, and the figures are considerably less than in the corresponding week last year and than the median value for the last nine years. There were fewer deaths from influenza in the 125 Great Towns compared with the previous week, while in London it fell there was an increase (from 2 to 13). In all the towns or groups of towns from which figures are available there was a decided increase in deaths from influenza compared with the corresponding week last year. Although influenza has not been observed in epidemic form either in Europe or in the U.S.A., a number of mild outbreaks have been reported in Switzerland, Hungary, and Denmark, as well as a slight increase in influenza mortality in the towns of Germany and of England and Wales.

## Measles and Whooping-cough

In the 125 Great Towns there were 38 deaths from measles, compared with 67 in the previous week, of these 12 (23) occurred in London, 3 (5) in Liverpool, 4 (3) in Manchester. The figures in parentheses denote the deaths in the previous week. The London epidemic appears definitely to have passed its peak, 2,095 cases were reported from the L.C.C. elementary schools compared with 2,477 last week, and the average daily admissions to the L.C.C. fever hospitals dropped from 103 to 92. The number of cases of measles under treatment in the L.C.C. fever hospitals on April 1 was 2,339 compared with 2,284 on March 25 and 2,079 on March 18. The increase of cases under treatment is likely to be maintained for a week or two as severe and complicated cases may remain in hospital for several weeks. On April 1 there were under treatment in the L.C.C. fever hospitals 1,128 (1,182) cases of diphtheria, 838 (844) cases of scarlet fever, 307 (312) cases of whooping-cough. The figures in parentheses refer to the numbers in the previous week. Notifications in the eleven metropolitan boroughs in which measles is notified were, for the week ended April 2, 1,113 distributed thus: Battersea 144 (136), Bermondsey 76 (94), Finsbury 30 (28), Fulham 77 (73), Greenwich 136 (112), Hampstead 47 (105), Lambeth 264 (322), St. Pancras 123 (171), Shoreditch 35 (38), Southwark 124 (202), Stepney 57 (54). The figures in parentheses denote the numbers for the previous week.

In Scotland 1,421 cases were notified compared with 1,495 in the previous week, the figures for Glasgow were 692 (893), for Aberdeen 246 (210), Dundee 224 (132), Edinburgh 102 (78), Paisley 29 (51). The figures in parentheses refer to the numbers in the previous week. During the week there were in Scotland 19 deaths from measles compared with 36 in the previous week, of these 12 occurred in Glasgow, in the previous week there were 27 deaths in Glasgow and 1 in Edinburgh. In Northern Ireland there were 63 cases of measles, of which 60 were in Belfast alone, compared with 80 and 76 respectively in the previous week, while there were 8 deaths (all of which were in Belfast) compared with 12 in the previous week. During the week under review there were 2 deaths from

measles in Eire, both in Dublin. The available figures appear to indicate that the incidence and mortality of measles are alike decreasing. Mortality from whooping-cough on the other hand seems to be on the increase, the deaths for the week were 28 (13) in the Great Towns, 4 (1) in London, 4 (1) in Scotland, 1 (1) in the 13 principal towns of Eire, 1 (0) in the 10 principal towns of Northern Ireland.

## Small pox

In the week ended April 2 there were 162 cases of small pox in Hong Kong with 112 deaths compared with 151 cases and 131 deaths in the previous week. In Calcutta there were in the week ended March 26, 208 (261) cases of small pox with 161 deaths, and in Bombay 164 (212) cases with 100 deaths. The figures in parentheses denote the numbers for the previous week.

## Typhus

In the week ended March 26 there were in Morocco 254 (372) cases of typhus with 14 deaths, of these 82 (122) occurred in Marrakesh, 26 (78) in Casablanca, 21 (20) in Rabat, 6 (6) in Agadir. The figures in parentheses refer to the number of cases in the previous week. In the same week there were in Egypt 98 cases with 11 deaths compared with 85 cases reported in the previous week. The disease appears to be widely spread there being 32 cases at Qena, 12 at Giza, 3 at Cairo, and 3 at Alexandria.

## Medical News

A meeting of the Medical Legal Society will be held at 26 Portland Place W. on Thursday, April 28 at 8.0 p.m. when a paper will be read by Mr. William Laton on "Medical Legal Aspects of the Matrimonial Causes Act 1957".

A meeting of the Royal Microscopical Society will be held at B.M.A. House, Tavistock Square W.C. on Wednesday, April 20 at 5.30 p.m. when papers will be read by Prof. R. Ruegjes Gates, F.R.S. on "The Structure of the Chromosome" and by Dr. Miles Johnston (communicated by Dr. J. A. Murray, F.R.S.) on "Some Methods of Preparing Fish Otoliths for Examination".

The planning of hospitals will be discussed at a seasonal meeting of the Royal Sanitary Institute at the new Pervale Maternity Hospital, Western Avenue, Ealing, on Thursday, April 21 at 2.30 p.m. The discussion will be opened by Mr. L. G. Pearson, who will deal with the architectural aspect, and by Dr. James Ferguson and Dr. Thomas Orr, who will deal with general hospitals and maternity hospitals respectively. The chair will be taken by Professor J. M. Munro Kerr. Before the meeting at 11.20 a.m. an inspection will be made of the hospital.

The annual Students' Club ball of the Charing Cross Hospital Medical School will be held on Tuesday, April 26 at Grosvenor House, Park Lane W.

The annual congress of the Ophthalmological Society of the United Kingdom will be held at the Royal Society of Medicine, 1 Wimpole Street W. on Thursday, Friday, and Saturday, April 28, 29, and 30, under the presidency of Dr. Gordon M. Holmes, F.R.S. The morning of the first day will be devoted to a discussion on differential diagnosis of the causes of exophthalmos; in the afternoon papers will be read, and in the evening the annual dinner of the society will take place at the Langham Hotel. The whole of the second day from 10 a.m. to 10 p.m. will be given up to the reading of papers, with the exception of a demonstration by Mr. A. Sorsby. On April 30 papers will be read in the morning from 10 a.m. the annual general meeting of the society will be held at 12 noon, and the proceedings will close with a visit to the General Post Office. Full particulars of the congress may be obtained from the secretary, Mr. L. H. Savin, F.R.C.S., 7 Queen Street, Maffair, London W.1.

doubtful value and may even be harmful. They do not stimulate the testicular secretion and may even cause disuse atrophy of the secreting cells. The injection of the gonadotropic hormone of the pituitary is less objectionable, but in view of the potential production of anti-hormones and of the possible role of injected hormones in the causation of tumours should be used with great caution.

### 314 Dupuytren's Contracture

That in addition to occupational trauma as a determining cause constitutional and hereditary factors play a part in the production of Dupuytren's contracture is shown, according to M. CONSTANTINESCU (*Zbl. Chir.*, January 22, 1938, p. 191), by the reports in the literature of nine cases (to which a tenth is here added) of its congenital occurrence, and also by its not infrequent familial incidence—in four out of twenty-two cases studied by Krogus and in twelve out of thirty-one investigated by Schroder. There is also evidence that organic nervous lesions are concerned in certain cases, the contracture has been noted in sufferers from tabes, general paralysis, and syringomyelia after injury to the brachial plexus or ulnar nerve, in association with lesions of the eighth cervical and first dorsal segments, and in combination with the Horner syndrome. In three of four brothers affected Testi was able to find at necropsy evidence of syringomyelia. Constantinescu's patient, a boy aged 15, in whom the deformity caused little or no inconvenience, had been delivered through a flat contracted pelvis, his genital organs were hypoplastic, but the blood calcium was normal. The deformity was bilateral.

## Therapeutics

### 315 Copper in Pulmonary Tuberculosis

N. BONARRIGO (*Rass. Fisiopat. Clin. Ter.*, November, 1937, p. 670) records his observations on twenty cases of pulmonary tuberculosis in patients aged from 24 to 64 who were treated by weekly intravenous injections of 5 c.c. of a double cyanide of copper and potassium. He found that favourable results were obtained in early cases and in those running a slow course. No symptoms of intolerance were observed in the form of digestive or renal disturbances or skin eruptions such as may occur in treatment by gold salts.

### 316 Vitamin B<sub>1</sub> in Herpetic Keratitis

J. NITZULESCU and E. TRIANDAF (*Brit. J. Ophthalm.*, December, 1937, p. 654) report the effect of injections of vitamin B<sub>1</sub> in two cases of herpetic keratitis. The pain was rapidly relieved, the progress of the condition arrested, and cure accelerated. The authors regard the vitamin as exerting a specific action on the trophic functions of the nerves. In these two patients there was no clinical or other evidence of avitaminosis.

### 317 Light Therapy and Carbohydrate Metabolism

L. PINCUSSEN (*Arch. phys. Ther.*, December, 1937, p. 750) has found that ultra-violet and visible rays greatly influence the carbohydrate metabolism, the most obvious effect was a lowering of the blood sugar. He was able to prove in animals that the decrease of the blood sugar goes side by side with an increase of the glycogen content of the liver and muscles and with a decrease of the lactic acid so that the ratio of carbohydrate to lactic acid increases and the glycogen which has disappeared from the blood is stored in the tissues. The rays therefore act in the same way as insulin. The effect of the irradiation depends however on its wave-length and the amount of glycogen in the liver and muscles of irradiated animals.

depends on the combination of ultra-violet and visible rays. The highest content of carbohydrate in the tissue and the highest ratio of carbohydrate to lactic acid appear after the application of one part of ultra-violet and nine parts of visible light. In diabetic patients the blood sugar decreases in the same way as in normal individuals. The sugar and acetone bodies in the urine decrease and may disappear completely. Here, too the effect depends on the quality and quantity of the irradiation.

## Laryngology

### 318 Air Cells of the Petrous Bone

J. G. WILSON, J. P. GAARDSMORE and B. J. ANSON (*J. Laryng.*, November, 1937, p. 746) present an anatomical study of a normal right temporal bone which was decalcified and cut serially in the horizontal plane at a thickness of 25 microns. The sections were stained, and a reconstruction of the air cells was made by the Born wax plate method. There are two groups of air cells. A first group the epitympanic cells, are extensions of the mastoid air cells over the labyrinth. A second and more important group arise from the tympanic cavity independently of the mastoid cells. These are called tubal cells because they are closely related to the tympanic end of the Eustachian tube. From that point the tubal air cells form an almost complete ring around the carotid canal, they partly surround the cochlea, and one group reaches the very tip of the petrous bone. Photographs of the wax models bring out the difficulty of surgical approach to the tubal cells as compared with the ease of opening the epitympanic cells by the mastoid route. When suppuration persists in the tubal cells the localization of the disease focus is extremely difficult, and radiographs are not very helpful, according to the authors. The general history of the case and the location of the pain are more important. The pain of petrositis is orbital and temporal—that is, in the area supplied by the ophthalmic division of the trigeminal nerve. The recurrent meningeal branch of the ophthalmic nerve supplies the dura covering the petrous pyramid, and the pain is probably reflex from this branch.

### 319 Treatment of Ménière's Disease

H. OLIVECRONA (*Schweiz. med. Wschr.*, February 5, 1938, p. 125) restricts the term Ménière's disease to a chronic condition of intermittent paroxysms of vertigo with vomiting, nystagmus, and deafness and tinnitus in the affected ear, without demonstrable aural anatomical changes, he is inclined, however, to include a few rare cases in which deafness is absent but noises are heard in the ear. As "symptomatic Ménière's disease" he groups cases associated with morbid conditions, affecting structures from the vestibule to the vestibular nuclei, which might cause the symptoms, bulbar tumours are most commonly concerned than acoustic tumours. The differentiation from true Ménière's disease is easy, save when the symptoms are due to aneurysm of the vertebral artery or one of its branches. Pseudo-Ménière's disease is distinguished as the occurrence of attacks indistinguishable from true Ménière's disease in persons in whom tinnitus and lateral deafness are absent, here the prognosis and response to symptomatic medication are generally good. In true Ménière's disease Olivecrona is not convinced of the value of any of the numerous drug and dietetic treatments. He favours trial of (1) the dehydrating treatment (pilocarpine and diuretics, followed by a salt poor diet with restricted intake of fluid) based by Meyer and Dederich on their attribution of the disease to fluid retention, or (2) Furstenberg's sodium depletion by restriction of salt intake and the exhibition of ammonium chloride. In Olivecrona's hands, as in Dandy's section of the vestibular nerve, with preservation of the cochlear nerve.

given good results. He prefers avertin or cyan to a local anaesthetic and he divides the middle third of the nerve. In his first five cases the vestibular nerve was completely severed for fear of injuring the facial. Four patients were cured and one improved. In sixteen later cases the whole of the acoustic nerve was divided in nine and the vestibular but not the cochlear nerve in seven (all of whom preserved their hearing). The sixteen were cured; there was no mortality but two had transitory and one permanent facial palsy. Collected statistics give only a small operative mortality. Dandy has seen no recurrence of attacks after section of the acoustic or vestibular nerve in 160 cases, ten with bilateral disease.

### 320 Oesophageal Perforations

P. GUSS (*Ann Otolaryng*, November 1937, p. 999) reports four cases of perforation of the cervical portion of the oesophagus and states that large perforations occur more rarely at the present day than formerly. On the other hand small perforations are commoner because oesophagoscopy is more often carried out. Pain in the neck region and rises of temperature are late signs and indicate an early mediastinitis. Subcutaneous emphysema is an early and valuable clinical sign. At first the air can be displaced by palpation of the neck tissues and made to reappear by asking the patient to swallow. A radiograph at this stage shows a large air bubble in front of the cervical vertebrae. The author advises immediate operation in all the cases using the technique described by Marschik. This consists in laying open the prevertebral space along the whole length of the neck and packing it lightly with gauze, the sterno-mastoid and carotid sheath being displaced backwards. The gauze packing is left for forty-eight to seventy-two hours. The operation exposes that tissue space in the neck which is directly continuous with the mediastinum below and is designed to prevent the onset of mediastinitis. Once mediastinitis has set in the patient practically always dies. In all four of his cases the perforation was due to an impacted foreign body, dentures in three cases and a piece of bone in the fourth. In each case an unsuccessful attempt had been made to remove the foreign body through an oesophagoscope. Immediately afterwards the foreign body was extracted through an external incision followed by the operation described above. One of the four patients died from mediastinitis, presumably because nearly three days had elapsed between the attempted removal by oesophagoscopy and the external operation.

### 321 Laryngeal Abscess

A. MONTEIRO (*Brasil med*, January 8 1938, p. 23) who records three personal cases in patients aged 5, 40 and 65 respectively, all of whom recovered states that laryngeal abscesses are uncommon. They are seen principally in males and may be internal or external the symptoms and treatment varying accordingly. The clinical course depends on the histological localization of the inflammatory process. Its duration ranges from a maximum of ten to fifteen days to a minimum of two or three days. The prognosis should always be guarded as a laryngeal abscess may give rise to pulmonary abscess, pyopneumothorax, or polyarthritis.

### 322 The Labyrinth in Otosclerosis

From a study of the literature and his own investigations in the course of six necropsies F. R. NAGER (*Schweiz med Wschr*, January 22 1938, p. 83) gives the following account of the labyrinthine findings in severe diffuse otosclerosis. In addition to atrophy of the stria vascularis slight alterations of the cochlear spindle atrophy (in some cases) of ganglion cells and nerve fibres the most striking alterations are seen in the basal twist of the scala tympani in which there is an extensive new formation of lamellar bone filling the scala tympani almost up to the spiral

ligament and membrana basilaris. This is only noted in regions in which the otosclerotic transformation has reached the endosteum and penetration of the otosclerosis into the newly formed bone may be traced accordingly. The labyrinthine bony changes are not—as was formerly thought—solely the consequence of irritation by the surrounding morbid process or of venous stasis. The scala vestibuli has never been found the site of similar changes. Cortis organ may be normal, endolymph and perilymph may show some alterations, the membranous labyrinth and Reissner's membrane are unaffected. Otosclerotic penetration of the semicircular canals has not been observed but loci of endosteal thickening containing osteoid tissue may occasionally be found in their immediate neighbourhood.

### 323 Osteomyelitis of the Frontal Bone

P. D. PASTORE and H. L. WILLIAMS (*Proc Mayo Clinic*, January 5 1938, p. 7) report a case of osteomyelitis of the frontal bone secondary to acute frontal sinusitis. The patient, a girl aged 18, had been suffering for five weeks from symptoms of left frontal sinusitis which had been associated with headache and vomiting. Radiological examination revealed osteomyelitis of the frontal bone of spreading type with involvement of both frontal sinuses. An incision was made over the vertex from ear to ear and the entire frontal portion of the scalp was pushed down over the eyes. The bone was dissected from the dura leaving a bony ridge above the brow. Over the left frontal lobe of the brain there was a large epidural abscess with widespread granulation tissue. There was also some purulent discharge through the dura. The opening in the dura was enlarged with the cautery but more pus could not be found. The posterior walls of both frontal sinuses were diseased and both the frontal and ethmoid sinuses were filled with pus and infected granulation tissue all of which was removed. A large opening into the nose was made through the floor of both frontal and ethmoid sinuses and the openings were connected through the septum. Soft rubber tube drains were placed on each side from the incision in the scalp down through the nose and out through the nostrils. Rosenow's concentrated anti-streptococcal serum was diluted and poured freely into the wound. A vaccine made from the organism found in the diseased bone was later used daily for lavage of the wound. A ray examination six weeks after operation revealed no evidence of osteomyelitis. It is emphasized that removal of bone should extend well beyond the apparent limits of the disease and that complete elimination of the primary disease in the sinuses is essential. Cultures made from material from the periphery of the diseased area revealed the presence of an anaerobic streptococcus.

## Obstetrics and Gynaecology

### 324 Hyperemesis and Vitamin C

L. G. DAHLHEIM (*An Bras de Gyn*, January 1938, p. 18) describes a case of hyperemesis which was cured by the administration of vitamin C. The patient was a married woman of 29 who one month after the onset of amenorrhoea began to suffer from morning vomiting which became steadily worse until she was finally unable to swallow anything but tea and soft biscuits. She was losing weight becoming weaker every day and complaining of giddiness, tinnitus and tachycardia. On examination nothing worthy of note was discovered apart from some enlargement of the thyroid and tachycardia. For ten days a series of different treatments were carried out, including intravenous glucose and serum, Ringer's solution, insulin, bromides and atropine but without the least improvement. The patient then had some pyrexia and

oliguria, the urine was found to contain albumin, a few red cells, and bilirubin. At this stage the patient was given a first injection of vitamin C intravenously, the vomiting ceased the same day and did not recur for eight days, during which she continued to receive injections. She began to feel hungry, was able to get up, and felt and looked much better, the pyrexia and oliguria disappeared. The injections were discontinued for two days, but the patient became worse, so they were resumed, at the end of a fortnight the patient had gained 3 kilos. She was then given vitamin C orally, and from that time the pregnancy pursued a normal course. The author discusses the mechanism of the action of vitamin C and suggests that it exerts an action antagonistic to the thyroid but stimulating to the adrenals.

### 325 Blood Vessels in the Senile Uterus

V. PUGLIATTI (*Ann Ostet Gynec*, December 31, 1937, p 1429) has examined histologically forty-three uteri removed from nulliparae and multiparae, these included thirteen women still within the reproductive phase of life and thirty post-menopausal cases with ages varying from 47 to 86 years. He found that although previous pregnancies usually leave behind as an indelible sign an increase in the elastic tissue surrounding the vessels, especially the smaller vessels of the internal layer, this is not an infallible criterion, since it may also be found after other conditions, such as chronic inflammatory processes, even, though more rarely, in nulliparae. Moreover the type of menstruation, the general constitution, and other factors have some influence on the development of this elastic tissue. The author goes on to illustrate the common degenerative or hyperplastic processes which affect the intima and media of the larger vessels. He believes that arteriosclerosis is the underlying cause, but that in this case also local predisposing factors have to be taken into account.

### 326 Ophthalmic Indications for Abortion

A. FAVORY (*Progr med*, Paris, January 29, 1938, p 153) is of the opinion that pregnancy should always be terminated in the presence of retinitis of renal origin, not only the possibility of blindness but also the condition of the kidneys are the deciding factors. In retrobulbar neuritis, syphilis and nasopharyngeal conditions having been eliminated, induction should be considered. Myopia is often aggravated by pregnancy, and in these cases retinal haemorrhages and detachment sometimes occur. Pregnancy should be forbidden where there is already detachment in one eye. All forms of choroiditis, uveitis, and keratoconus are made worse, in the first of these abortion should be considered. In hereditary types of eye disease which may involve blindness the necessity for intervention is not yet generally admitted. Here the eugenic and legal aspects of the case must influence the decision.

### 327 Sterility due to Chronic Genital Infections

C. BECLERE and É. FRANÇOIS (*Bull Soc Obstet Gynec Paris* November 1937, p 709) have investigated the part played by chronic genital infections in the aetiology of persistent sterility. Of ninety-nine cases studied by them 71 per cent were women who had never been pregnant—that is their sterility was primary in type. Of these, one-quarter had congenital lesions and two-thirds had chronic genital infections. Of these infections half were gonococcal in origin and half were due to secondary infection following gonorrhoea. In the 29 per cent of women who had secondary sterility 90 per cent had chronic infections. In more than half of these women infection followed abortion or parturition the infections following abortion being twice as frequent as those after childbirth. In three-quarters of these cases of post-abortion or post-natal

infection the infecting organism was the streptococcus the gonococcus being responsible in only 25 per cent. In less than one-half of the cases of secondary sterility the infection followed some length of time after pregnancy. In these cases the infection was presumably sexual in origin, and evidence of gonococcal infection was found in three quarters of the cases. Routine examination by salpingography showed that in half of the cases of sterility there was a complete obstruction of both tubes, three quarters of these cases were of chronic infection, usually gonococcal. In one-fourth of all the cases the permeability of the tubes was diminished, here again chronic infection was the common cause, but the gonococcus was not so important. In the remaining fourth the permeability of the tubes was maintained, but often it existed only during examination as the result of increased pressure. Generally, in primary sterility, the infection is of sexual origin, in secondary sterility the infection is due to abortion or is of sexual origin. Infection after full-time parturition is less commonly the cause of persistent sterility.

## Pathology

### 328 Encephalitis Epidemica in Japan

R. IANADA (*Presse med* December 29, 1937, p 1889) gives an account of recent researches into the nature of the virus of encephalitis in Japan. Numerous experiments have defined the conditions necessary to a successful inoculation of the virus in various animals, the localization and duration of the infection, the resistance of the virus, and its immunological characteristics. It has been established that the Japanese strain of the virus differs from the American (St. Louis) strain. Monkeys and mice were inoculated with brain material or blood containing the virus of encephalitis, some survived and some died. Those which survived were given a second injection and most of them showed resistance to reinfection, though control animals injected with the same material succumbed. Japanese investigators have immunized mice, rabbits and goats with American virus and Japanese virus and have found that it is possible to immunize against the homologous virus and not against the other. These experiments seem to prove that the two strains of virus are, from an immunological point of view, different strains.

### 329 Salmonella Infection of Wild Rats

A. M. KHALIL (*J Hyg, Camb*, January, 1938, p 71) examined 750 wild rats trapped in Liverpool during 1936 for evidence of salmonella infection. About 70 per cent of the animals were of the large brown variety, probably *Rattus norvegicus* and 30 per cent of the small black variety, probably *Rattus rattus*. Portions of liver, spleen and gut were inoculated into tetrathionate broth incubated at 37°C for eighteen hours, and then plated on brilliant green-eosin agar. The strains isolated were identified by agglutination. Strains of salmonella were isolated from fifty-five rats (73.3 per cent). Since strains were sometimes isolated from more than one organ, eighty strains in all were collected. Of these, forty-five belonged to the enteritidis forty to the typhi-murum three to newport and one to the thompson type. A remarkable observation was made on the seasonal distribution of infection. Equal numbers of rats (250) were examined in each of the three month periods January to March, April to June and July to September 1936. In the first period forty-four infected animals were found, in the second period ten, and in the third period only one. The explanation is at hand for such an uneven distribution. As the author remarks it does not accord with the seasonal distribution of outbreaks of food poisoning in man.

# A patient at THE CLINIC said this:

Here is a statement which is of equal interest to the Medical Profession and to the Public. It was made very recently by a patient at The Clinic to someone unconnected with The Clinic in any way whatever, and it was purely by chance that the statement became known to the Trustees of The Clinic. The name and address of the patient are available to bona fide enquirers.

The Patient was a lady convalescing at The Clinic after an operation. She is keenly interested in medical progress. To one of her visitors she said: "There are eight floors, one of which is devoted entirely to maternity work, eight operating theatres which afford the surgeon every facility for the finest work, and a fully trained staff of some hundred nurses. The presence of two resident medical men in the building gives one the satisfying knowledge of being constantly as it were under the surgeon's eye. Another very important point which I think should be considered by the heads of every nursing home, is the care given to the feeding of the patients. Two special dietitians and six chefs provide a choice of menu for the convalescent which would rival a West End de luxe restaurant. THE CLINIC HAS AT LAST BROUGHT SOMETHING OF SCIENCE INTO THE NURSING HOME. I HOPE ITS EXAMPLE WILL BE FOLLOWED ALL OVER THE COUNTRY!"

Under its constitution the Company is bound to devote all surplus Revenue to the furtherance of its objects. Over £12,000 was so utilised in 1936-1937. Enquiries and visits from the medical profession are welcome and the Secretary will be glad to furnish further details.

There are eight operating theatres in the Clinic. The room rates which range from 10 guineas to 18 guineas (apart from a few suites at 25 guineas to 42 guineas).

**ADMINISTRATIVE COUNTY OF ESSEX****OLDCHURCH COUNTY HOSPITAL  
ROMFORD****APPOINTMENT OF OBSTETRIC SURGEON**

The County Council of the Administrative County of Essex invite applications for the above appointment from registered Medical Practitioners not over 45 years of age with special experience in the practice of obstetrics and gynaecology and holding the qualification of F.R.C.S. or M.C.O.G. to act under the direction of the Medical Superintendent of the Hospital.

The above Hospital has accommodation for 860 patients with maternity and gynaecological units comprising 10 beds in each unit and is equipped with all modern departments and has a visiting staff of consultants.

The salary will be at the rate of £600 per annum and will rise subject to satisfactory service by annual increments of £25 to £750 per annum together with full residential emoluments valued at £160 per annum. Residential quarters are not available at the Hospital for married men but applications from such persons who are prepared to provide their own accommodation in the immediate vicinity of the Hospital will not be debarred thereby. In the event of a non-resident appointment being made until residential quarters are available the value of the emoluments amounting to £160 per annum will be attached to the salary.

The person appointed will be required to devote his whole time to the service of the Council and to perform such duties and to furnish such advice and assist in carrying out his office as may be required.

The appointment will be held by the successful candidate during the pleasure of the Council and will be subject to such alterations of duties as the Council from time to time think fit to order and will be determinable by the officer by three months' notice in writing.

The person appointed will be required to pass a medical examination and to contribute 5 per cent of his salary and emoluments to the fund established by the County Council under the Local Government and Other Officers Superannuation Act 1922.

The appointment will be subject to the Council's Sick Pay Rules and Regulations a copy of which will be forwarded on application.

Applications stating age qualifications and experience together with copies of not more than three recent testimonials which will not be returned should be addressed to me and delivered at the County Hall Chelmsford not later than 10.15 am on Monday April 25th 1938.

E. S. HOLCROFT

Clerk of the County Council

County Hall Chelmsford

April 15th 1938

**BOROUGH OF HENDON****ASSISTANT MEDICAL OFFICER OF HEALTH  
AND ASSISTANT SCHOOL MEDICAL  
OFFICER (MALE)**

The Hendon Borough Council invite applications for the above post.

Applicants must be fully qualified Medical Practitioners and hold a Diploma in Public Health or an equivalent qualification.

The duties will be mainly in connection with the Council's Maternity and Child Welfare and School Medical Services but include other duties under the direction of the Medical Officer of Health.

The salary is £600 per annum rising by annual increments of £50 to a maximum of £650 with a car allowance of £50 per annum if the successful candidate provides his own car for use in connection with his duties.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act 1922 and the successful candidate will be required to pass a medical examination.

Applications in forms to be obtained from the undersigned together with copies of not more than three recent testimonials to be sent to the undersigned not later than the first post on Monday May 1st 1938.

Conveying directly or indirectly will be deemed a disqualification.

Dated this 15th day of April 1938

# ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in July, 1938

Candidates below the age of 25 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

At the end of three years' service, officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for post graduate study, to specialise, to take higher examinations and to obtain further qualifications.

Naval Medical Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers.

Copies of the regulations for entry and conditions of Service, including rates of pay, allowances and retired pay may be obtained from the Medical Director General of the Navy, Admiralty, SW 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than 31st May, 1938.

## ROYAL NAVAL DENTAL SERVICE

Applications are invited for the post of Dental Officer in the Royal Navy. Candidates must be registered under the Medical Acts and be of 25 years of age or under. They must hold a degree or diploma from a University or College of Surgeons and be recommended by the Dental Act of Medical Act and be required to attend at the Admiralty for interview and physical examination. Copies of the regulations for entry and conditions of Service, including rates of pay and allowances and forms of application may be obtained from the Medical Director General of the Navy, Admiralty, SW 1, and from the Deans of Dental Schools.

## LIVERPOOL COUNTY BOROUGH

### LOCAL EDUCATION AUTHORITY

#### SENIOR ASSISTANT SCHOOL MEDICAL OFFICER

Applications are invited for a Senior Assistant School Medical Officer in the Department of the Medical Officer of Health, Education Authority at a salary of £ 0 per annum.

Candidates must be registered medical practitioners and it will be considered an advantage if candidates have had experience of school medical work and also some administrative experience. The officer appointed will be required to reside within the city and devote his entire service to the Local Education Authority under the direction of the Medical Officer to the Local Education Authority and will not be allowed to undertake any private practice.

The appointment will be subject to the Local Government and Officers Superannuation Act 1928 and the Standing Orders of the City Council.

Form of application and list of duties may be obtained by forwarding a stamped addressed post envelope to the undersigned and the form of application together with copies of three recent testimonials should be received not later than April 30th and endorsed Senior Assistant School Medical Officer.

The canvassing of members of the Education Committee or the City Council is strictly prohibited and will be considered a disqualification.

Municipal Buildings, W. H. BAINES, Esq.  
Liverpool 2, Town Clerk and Clerk to the  
April 15th 1938 Local Education Authority

## BOARD OF CONTROL ENGLAND AND WALES

The Board of Control (Mental and Moral Diseases) have a vacancy for a Medical Officer as COMMISSIONER on the following staff.

Candidates should be experienced in the care and treatment of persons suffering from mental disease or moral defect.

The salary commences at £20 per annum and rises by 10 annual increments of £10 to £110 and then to £100 per annum. In the case of a candidate with special experience of the administration of mental institutions the corresponding salary may be advanced to a point not exceeding £15 above the maximum of the scale.

The appointment will be subject to the Local Civil Service Commission as to pension holidays, etc. and also in the case of women marriage, etc. and to certain conditions previously established in the Mental Hospital or Mental Deficiency Institution in which he is appointed with Civil Service for superannuation purposes.

Candidates are required to devote their whole time to the Public Service.

Canvassing through Members of Parliament or in other ways will render a candidate liable to disqualification.

Form of application with further particulars of the appointment may be obtained from the Secretary, Board of Control, Metropole Buildings, Northumberland Avenue, London W.C.2.

No application can be considered unless received on the preferred form not later than May 15th 1938.

## CITY OF BRADFORD

### ASSISTANT CITY PATHOLOGIST REQUIRED

Salary £500 per annum rising to £700 per annum by annual increments of £25.

The salary is subject to a deduction of 5 per cent under the terms of the Local Government and Officers Superannuation Act 1928, and the successful candidate will be required to pass a satisfactory medical examination.

Application form may be obtained from the Medical Officer of Health, Town Hall, Bradford, and should be returned to the undersigned not later than April 2nd 1938.

Town Hall, Bradford. N. E. FLEMING  
April 4th 1938

## NORFOLK COUNTY COUNCIL

### APPOINTMENT OF TEMPORARY MEDICAL OFFICER.

A vacancy exists for a temporary medical practitioner with special experience of mental deficiency in children.

The salary will be £100 per annum with travel expenses in excess of £10 with the Council's seat and the amount is expected to last for a period of six months.

The officer will be required to attend the County Medical Officer. The duties will be the examination of all child and adult cases in the county and the completion of the Board of Education Report Form for those who are mentally defective.

The appointment will be subject to one month's notice by either side.

Applications must be made on the prescribed form which can be obtained from the County Medical Officer, Public Health Department, 19 Thorpe Road, Norwich, to whom they must be returned accompanied by copies of not more than three testimonials not later than April 15th 1938.

H. C. DAVIES  
Clerk of the County Council  
County Offices, Thorpe Road, Norwich

FIFTH EDITION ENTIRELY REVISED and RESET

Large Octavo 1,076 pages, with 1264 Illustrations including 5 Coloured Plates

Cloth

Price 52s. 6d. net

The six years since the last edition of this work constitute a period of unusual activity in everything of the nature of gynaecological physiology and structure and in applying such knowledge to the cure of disease conditions. This revision has extended also to our reference resources giving a much better understanding of their possibilities. This new edition has been extensively rearranged and rewritten to cover the new knowledge. About 200 new illustrations have been added.

**263, High Holborn****HENRY KIMPTON****London, W.C.1**

## **PURE enjoyment with this filter tip**

In du Maurier cigarettes the full flavour of Virginia tobacco can be enjoyed in the certainty that no throat irritants, no "bits" of tobacco, nothing in fact but the pure and fragrant smoke can pass through the filter tip. The five protective layers in the filter tip are there to guard the health of smokers. du Maurier can be bought either cork-tipped in the red box or plain tipped in the blue box.

# **du MAURIER**

*the perfect cigarette with the exclusive filter tip*

TEN FOR SIXPENCE—TWENTY FOR ONE SHILLING

## They call it "the doctor's car"

THE suitability of the Wolseley 14.56 h.p. for the work a doctor has to do is so striking that large numbers of practitioners all over the country have chosen it above all others. A doctor's work calls for —

**EASY STARTING**—In the Wolseley 14.56 h.p. a thermostatically controlled water system does away with warming up delays and sluggish pulling. A 12 volt electric system and twin batteries ensure ample starting energy.

**ROOMINESS**—Quick and easy exit through wide doors, fresh air renewal every 60 seconds and anatomically correct seating mean freedom of fatigue on even the longest day.

**NIGHTWORK**—Powerful headlamps, twin fog lamps, stop and reversing lamps and duplex screen wipers lessen the strain of dark and rainy nights.

**ECONOMY**—24 to 28 miles per gallon is good for a 14 Wolseley stabilised production policy, lower depreciation.

**QUIET**—Body, door and floor are completely insulated from noise—the interior from fumes.

**APPEARANCE**—The Wolseley 14.56, either as a Saloon or in its Salon de Ville form, is a distinguished, handsome car—very indicative of the standing of its owner.

BETTER BUILT A BRITISH CAR

The price of the 14.56 h.p. Saloon is £1,100. The 14.56 h.p. Super Six is £1,300. The 14.56 h.p. Salon de Ville is £1,400.

## Help yourself .. and please yourself

"Help yourself to Cigarettes." As a business woman and hostess I know that invitation to be a most useful conversational opening . . . particularly if the Cigarettes are Player's, because "all the world and his wife" seem to prefer Player's, either "Medium" or "Mild" So I always offer a box of each with the injunction "Help yourself and please yourself" knowing for certain they will

BOTH BLENDS ARE CORK-TIPPED OR  
PLAIN 10 FOR 6<sup>D</sup> 20 FOR 11½<sup>D</sup>

*Player's Please*

# Special terms to the MEDICAL PROFESSION

**20**  
equal monthly  
payments will  
buy any new car!

Among the facilities to be obtained at Henlys are special car-purchase terms for Doctors, by which any new car can be bought from Henlys and paid for by 20 equal monthly payments. The terms—the most favourable available anywhere—apply to any model or make of new car. (Henlys are distributors for S.S., Jaguar, Rover, Alvis, Austin and Morris, and agents for Morris, Riley, Daimler, Humber, Hillman, Armstrong, etc.) Any car will be taken in part exchange—and if your choice is a used car, Henlys offer the largest selection in the country, together with 7 days' free trial and a guarantee with every car costing more than £100. Write, phone or call no. for further particulars.

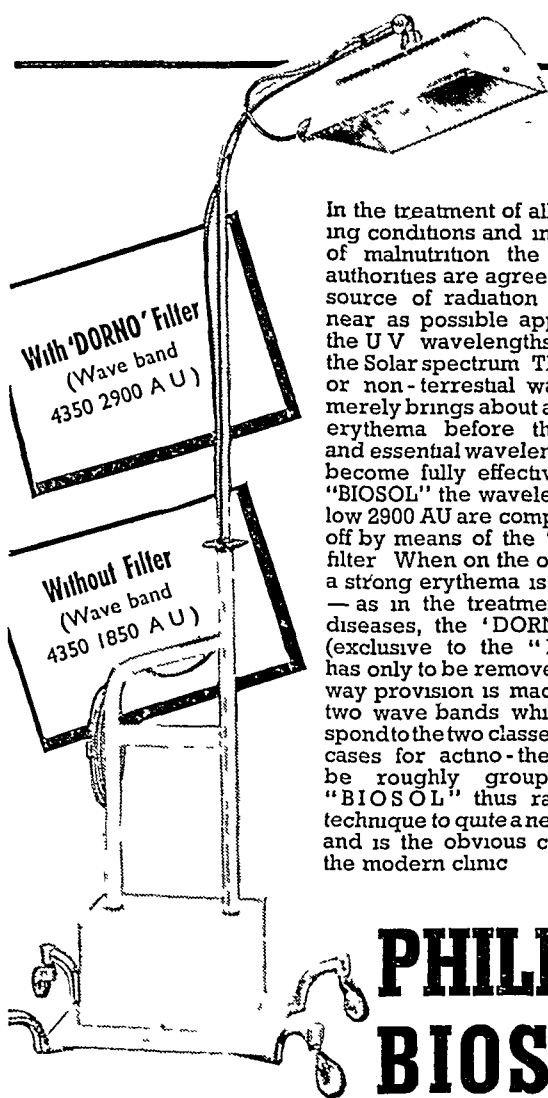

**choose your car at HENLYS**

To give you a better

Therapeutic

result...

In the treatment of all debilitating conditions and in diseases of malnutrition the foremost authorities are agreed that the source of radiation should as near as possible approximate the U V wavelengths found in the Solar spectrum. The shorter or non-terrestrial wave-band merely brings about a too rapid erythema before the longer and essential wavelengths have become fully effective. In the "BIOSOL" the wavelengths below 2900 AU are completely cut off by means of the 'DORNO' filter. When on the other hand a strong erythema is required—as in the treatment of skin diseases, the 'DORNO' filter (exclusive to the "BIOSOL") has only to be removed. In this way provision is made for the two wave bands which correspond to the two classes in which cases for actino-therapy can be roughly grouped. The "BIOSOL" thus rationalizes technique to quite a new degree and is the obvious choice for the modern clinic.

# A REMARKABLE MILK MODIFIER

Now being extensively used  
throughout the country after  
independent clinical tests by  
over three hundred physicians

**C**LINICAL TESTS recently conducted all over the country have led physicians to take a keen interest in Kao—a blend of soluble carbohydrate used primarily as a milk modifier.

Kao has been well known abroad for many years and is specially recommended by Professor Marnett in his book "Infant Nutrition". More recently samples of Kao were sent to a number of physicians in this country, with a request that they should test it out in their own practices.

Reports were received from over three hundred physicians, giving most impressive case histories of successful results obtained with Kao in the treatment of premature infants, and of infants and children who had previously suffered from marasmus, ketosis, constipation, diarrhoea and all kinds of digestive and nutritional disorders.

## *Within the reach of poor people*

As a direct consequence of these tests Kao is now being recommended extensively by physicians. It is sold at a price within the reach of poor people. A 1 lb tin, costing 1/3, provides a ten days' supply for a three-months-old baby—a cost of about 11d a day. The price of the 2-lb tin is 2/-.

### ANALYSIS OF KAO

Dextrose	23.31%
Maltose	10.10
Dextrin and Malt-Dextrin	35.11
Invert	3.50

# OVALTINE

IN SICKNESS AND CONVALESCENCE

THE impairment of digestive powers which is commonly met with in the feverish patient, combined with the lack of desire for food often aggravates the difficulty of adequately replacing the increased loss of energy and destruction of tissue which occur

Ovaltine provides a satisfactory solution to the problem of alimentation in many cases of sickness and in the stage of convalescence after severe, prolonged and debilitating illnesses, where an easily assimilable, palatable and concentrated nutrient is required. It is always acceptable

Ovaltine replaces with advantage the ordinary milk preparations which so often prove distasteful to the invalid. Prepared from full-cream milk, eggs and malt extract in carefully balanced proportions, it provides complete nourishment in the most readily assimilable form

## Pleasure Cruises . . .

3rd March, 1938

Messrs Kaylene, Ltd., Waterloo Road, London, N W 2

Dear Sirs,

I have to thank you for the samples of KAYLENE and COLONOL LIQUID PARAFFIN, which arrived this morning

It may be of interest to you to learn that KAYLENE-OL is an admirable prophylactic for the dysenteries and other intestinal infections common in hot countries. I invariably prescribe it to patients who are going for a holiday in the countries around the Mediterranean littoral, or pleasure-cruising

I think it probably acts by preventing injury to the intestinal mucosa in patients who evaporate a lot of fluid from the skin and, in the case of amoebic dysentery, by hindering the *Entamoeba Histolytica* from entering the crypts of Lieberkuhn by occluding them with an oily film

Patients who use it systematically every day as a prophylactic remain singularly free from the numerous troubles arising from the exuberant bacteriological flora of the intestine which is the rule in hot countries

I am guided in my opinion largely by personal experience. I have had dysentery seven times and each time was definitely associated with the running short of my usual prophylactic dose. I do not know of anybody ever contracting dysentery while maintaining the regular daily prophylactic dose of KAYLENE-OL

Yours faithfully,

Signed

, M D

## General Rheumatoid Conditions

'Calsiod' (Calcium ortho-iodoxybenzoate) provides the practitioner with a unique agent for the relief of pain, swelling, and muscle spasm in arthritis and rheumatoid conditions generally

### CALSIOD Brand TABLETS

In addition to its therapeutic value in arthritis, 'Calsiod' has a wide field of usefulness as a palliative in the many ill defined conditions which are loosely grouped under such terms as lumbago rheumatism neuritis etc

Calsiod is safe and non habit forming Therefore in unresponsive cases the dosage may be increased according to the tolerance of the patient

## Spring Tonic

"The proof or disproof of a drug's efficacy rests finally on the test in patients"

(*Lancet*, Oct 21, 1933)

By this ultimate test physicians for many years have proved that Neuro Phosphates is a palatable and efficient tonic in those ill-defined pathological conditions characterized by nervous debility, loss of appetite, and want of tone generally

### NEURO PHOSPHATES (Eskay Brand)

Each dose (two teaspoonfuls) contains in acid state Sodium Glycerophosphate 2 grs Calcium Glycerophosphate 2 grs and Strychnine Glycerophosphate 1/64 gr

IODINE OINTMENT

## "IODEX" BRAND

This ideal presentation of iodine is even more active than the Tincture, has greater inflammation-reducing, resolvent, and antiseptic properties, yet is entirely bland and non-staining, and it conserves unimpaired the vital qualities of the skin "Iodex" can therefore be applied with perfect confidence wherever an iodine ointment can be of service, even upon mucous or extremely sensitive surfaces

**Method of Application**—Wherever possible the ointment should be gently rubbed into the skin until its colour disappears. Where rubbing is inadmissible it may be liberally applied under a light loose bandage. Tight and air excluding bandages should never be employed

Samples sent to Medical practitioners on request  
MENLEY & JAMES, LTD, 64, Hatton Garden, London

## "Iodex" in Liquid Form

Liquid "Iodex" is of marked service in nasal catarrh, pharyngitis, tonsillitis, and in pre- and post-operative conditions of the nose and throat. It may be sprayed upon the throat or into the aural or nasal passages, with entire confidence in its suitability and efficiency, and its markedly resolvent properties and antiseptic virtues. The irritating and corrosive drawbacks of the ordinary iodine solutions are entirely eliminated

# CRUNCHY FOODS AND SALIVATION

---

The proper insalivation of food is held by many physiologists to be an important factor in digestion on account of the action of ptyalin in partially converting starch.

For this reason they consider that the normal diet should include a proportion of hard, dry foods, which demand thorough mastication and thus induce copious salivation.

Ryvita is a daily bread of hard, friable consistency. It therefore supplies a valuable factor which civilised dietaries too often lack. Free samples of Ryvita for distribution to patients will gladly be supplied on request.

# Convalescence

In convalescence a tonic is required that will co-operate with, and augment, the natural recuperative powers of the body, rather than one which will have only an immediate stimulating effect. In the latter case there is always the danger of disappointment, due to an artificial improvement that the natural powers are unable to stabilise.

Medical evidence extending over many years has established the value of Sanatogen in promoting convalescence. In "The Elements of Pharmacy, Materia Medica and Therapeutics", Sir William Whitla writes —

*"The interesting and valuable researches conducted by Tunncliffe and Beddoes upon metabolism, in which Sanatogen was experimented with, establish the fact that its organic phosphorus is almost entirely assimilated when the food is administered in the amount necessary for the needs of the body. When given in addition to other food, the amount of nitrogen and phosphorus retained in the organism is increased, the tissue metabolism is more complete, the constituents of the ordinary food being more thoroughly utilised, appetite is increased and the body weight augmented."*

Similarly gratifying observations are constantly being notified, and, as Sanatogen is entirely free from fats, sugars and carbohydrates, it can safely be prescribed in all types of cases. It is rapidly and easily digested and assimilated, even in cases exhibiting severe gastric inflammation, and for this reason it is a valuable addition to enemata. It can be added to any non-acid beverage or food, and, consequently, monotony in its administration can always be avoided.

## Vitamin Concentrate or Natural Food?

The normal daily dosage of Bemax, i.e.,  $\frac{1}{2}$ -ounce, provides 200 International units of Vitamin B<sub>1</sub>, which is from four to ten times as much as the recommended daily dosage of certain Vitamin B<sub>1</sub> "concentrates" advertised to the medical profession. If a higher intake is required, it is possible to supply as much as 600 to 800 units of Vitamin B<sub>1</sub> daily by the administration of three to four tablespoonfuls of Bemax, and thus in an entirely natural form at only a fraction of the cost of concentrates.

The Vitamin B<sub>1</sub> potency of Bemax is assured by biological assay of every day's output, and is from 12-15 International Units per gramme, about 400 units per ounce.

# BEMAX

A unique natural source of accessory nutritional factors

Vitamin B <sub>1</sub> —400 International Units per ounce	Vitamin E—the richest natural source
Vitamin B <sub>2</sub> —Flavin present in B <sub>1</sub> -rich supply	Phosphorus—330 mg per ounce
Vitamin A—280 International Units (as retinol)	Magnesium—53 mg per ounce
	Iron—3 mg per ounce
	Copper—0.45 mg per ounce

## VITAMIN B<sub>1</sub> IN FOODS

Biochemical J, 1935, and other sources

The figures represent International Units per ounce

**T**AKA-DIASTASE is a very potent starch liquifying enzyme which under conditions of temperature and moisture approximating to those in the normal stomach will render soluble the equivalent of 300 times its own weight of starch in ten minutes and much more during the normal period of digestion.

The outstanding clinical indication for Taka Diastase is in the treatment of so called amylaceous dyspepsia, or as it is sometimes termed intestinal carbohydrate dyspepsia. In this condition it is often advantageous to supplement the natural digestive enzymes with Taka Diastase in order to promote the complete digestion of the carbohydrates. Taka Diastase supplements the action of the ptyalin of saliva and as it is not permanently inactivated by the acid gastric secretion it is also capable of exerting a diastatic action in the intestinal tract.

● Taka-Diastase is supplied as powder, tablets or liquid. Tablets are also available containing Taka-Diastase with pepsin, pancreatin or strychnine. It is also obtainable as an elixir with bismuth, mucosinica and hydrocyanic acid. Further particulars will be sent on request.

BRAND & CO., LTD., SOUTH LAMBETH ROAD, LONDON, S.W. 8

## PROTECTS *Against Infection*

In comparative studies made under properly controlled conditions Metaphen has been shown to be from 86 to 1500 times more germicidal against *staphylococcus aureus* than five other commonly employed antiseptics including mercuric chloride and tincture of iodine. Against other common pathogenic organisms Metaphen also demonstrated its marked superiority over all of the drugs tested. Furthermore Metaphen was found to be 10% more effective for surface skin disinfection and 87% more effective for deep skin disinfection than tincture of iodine (*Annals of Surg.* 93:537-597). In addition to its great

bactericidal power Metaphen has other important advantages. It is non-toxic and non-irritating; does not coagulate serum or tissue albumins and its solutions are stable when exposed to air. Metaphen is supplied through pharmacies in a variety of useful forms including TINCTURE METAPHEN, METAPHEN 1500 SOLUTION and METAPHEN 12500 SOLUTION. Requests for professional literature are invited.

# To add to the value of Milk

Milk is recognised as one of the "protective foods"—that is why the Chief Medical Officer to the Board of Education has described the day when the Milk Scheme was introduced as a red-letter day in the history of School Hygiene

Milk is one of the richest dietary sources of those important minerals Calcium and Phosphorus. The part played by these elements in promoting the sound growth of bones and teeth and in giving a healthy tone to muscles, nerves and capillaries, is well known. But it is also known that Calcium and Phosphorus cannot be fully absorbed where there is a deficiency of vitamin D in the diet. Milk, especially winter milk is, in common with most foods, a comparatively poor source of Vitamin D. To derive the full benefit from the glass of milk therefore a capsule of Crookes Halibut Oil—a reliable and carefully standardised preparation—should be taken also. This will ensure that the valuable mineral constituents of the milk—the constituents that give it a peculiar character as a health food shall be made available to the body.

## THE PLACE OF BRAN IN THE TREATMENT OF COMMON CONSTIPATION

WHEN dealing with a case of common constipation traceable to a deficiency of "bulk" in the diet, the first thought is naturally "How can the daily intake of bulk most conveniently be increased?"

Fruit and vegetables, of course, supply a partial answer to the problem — but it is not infrequently found that these foods alone are not a sufficient corrective unless eaten in unappetisingly large quantities

For this reason many nutritional authorities today advise giving prepared wheat bran in the pleasant form of Kellogg's All-Bran

### *An attractively crisp breakfast cereal*

All-Bran is an attractively crisp cereal which most patients find a pleasant addition to their normal breakfast menu. The fibrous bulk in All-Bran is of the same type as that derived from vegetables and fruit, but has the advantage of being less easily broken down during digestion, and its action is therefore more effective and

thorough. All-Bran is, moreover, an excellent source of both Vitamin B and iron, which add greatly to its dietetic value.

All-Bran is intended to be eaten daily, like an ordinary breakfast cereal. The great value of All-Bran is that it absorbs water like a sponge. This water-softened mass gently but effectively aids elimination. Eaten regularly, it promotes a thorough evacuation of the bowel-contents in a natural manner that gives real relief and freedom from strain.

All-Bran may with advantage be prescribed in all cases where additional bulk in the diet is indicated. It may be eaten with milk or cream or cooked into scones, bread, etc. It may also be sprinkled over salads or other foods. To assure maximum effectiveness plenty of fluid should be taken, preferably between meals. All-Bran is obtainable from all reliable grocers. A packet will be sent free on request to any qualified practitioner. Inquiries should be addressed to Kellogg Company of Great Britain Ltd, Stretford, Manchester.

*Kellogg's All Bran is most palatable served with plenty of milk or cream. Many like it sprinkled over their favourite breakfast cereal.*

## SOME PROBLEMS IN PSORIASIS\*

BY

JOHN T. INGRAM, M.D., F.R.C.P.

*Physician in Charge of the Skin Department The General Infirmary at Leeds*

We have perhaps been too ready to admit that psoriasis is an incurable disease of unknown aetiology and to console ourselves with the suggestion that it only affects the healthy. I doubt if any of these statements are true. Whether they are true or not it is a fact that psoriasis, one of the commonest of skin affections, imposes on the sufferer a burden which only too often he carries through life and which is readily understood and implied by the term European lepra, its name in olden times. The disorder merits our constant attention and untiring effort in its relief and it is obviously fatuous to dismiss it as incurable when we all know that if the patient can be transferred to a hot and sunny climate the psoriasis spontaneously disappears.

In considering some of the problems associated with this subject and in particular problems of treatment I must pass over the ordinary and accepted facts. I would however like first to deal with one or two points which seem to me to merit attention. We are all very familiar with the silvery scaling as a clinical feature of psoriasis and with the characteristic distribution on elbows, scalp, knees and extensor surfaces. It so happens however that many cases of psoriasis come to us for the first time having had some treatment with ointment which has removed most of the scaling and upon occasion psoriasis does affect other than the typical sites. Patients with a recent eruption on an atypical site may not mention or may not associate it with old-standing chronic lesions on typical areas which may thus be overlooked.

More important than the silvery scaling is in my opinion the colour of psoriasis which is an admixture of red and brown—something approaching salmon red—and the demarcation of the lesions themselves. No matter what variation the eruption of psoriasis may take these two features are fairly constant. There are only two or three other common scaling erythemata which appear as generalized eruptions—namely seborrhoeic dermatoses, pityriasis rosea, and squamous eczematous eruptions—and none of them presents those two characteristics. It is therefore quite easy to make a diagnosis of psoriasis in the vast majority of cases even in the absence of the typical scaling and the typical sites.

### Problems in Diagnosis

Though psoriasis is commonly symptomless the majority of patients if questioned will admit to a certain amount of itching particularly when they are warm or are in bed. In a proportion of cases probably something approaching

30 per cent itching may be very severe. This feature would seem to depend largely on the temperament and nerves which make up the subject rather than the psoriasis itself except in relation to psoriasis of the perineum and various mixed reactions to which I will refer later.

Attention must be drawn to the difficulties in diagnosing psoriasis when it involves certain particular sites. In the majority of cases psoriasis will exist elsewhere than upon the atypical sites and the diagnosis will be clear out in rare instances limited sites alone may be involved and may cause some difficulty. Sometimes a patient not associating an old chronic eruption on elbows and knees with a recent affection of the face or perineum may not mention the chronic trouble thus unintentionally misleading the doctor.

**Scalp**—Commonly psoriasis of the scalp is more readily diagnosed by palpation than by inspection. The eruption consisting of well demarcated thickly scaling lesions feels like a miniature mountain range and quite unlike any other scalp affection. Occasionally however psoriasis involves the whole scalp in which case there is a diffuse scaling erythema which may only with difficulty be differentiated from a simple scurf. Careful examination may disclose at the hair margins the colour and characteristic demarcation of the eruption but this may be absent. If psoriasis elsewhere there is no question but that such a condition would also be psoriasis but should the eruption be limited to the scalp then difficulties may arise. I think it is quite wise to assume that any chronic dry scaling scurfiness of the scalp which does not readily respond to ordinary anti-seborrhoeic measures such as salicylic and salicylic ointment or perchloride and resorcin lotion and spirit shampoos is likely to be psoriasis or at all events may respond to anti-psoriatic treatment.

**Face**—Contrary to most teaching and most textbooks it is my experience that psoriasis of the face is very common. Whatever the explanation of this may be and whether or not it is a peculiarity of the district, I never have the slightest difficulty in producing cases of facial psoriasis to demonstrate to students. It is wise to bear this in mind for it has not been uncommon in the past for practitioners to console their patients by saying that the affection never involves the face. Psoriasis of the face rarely suggests that diagnosis to the uninitiated. I commonly have the appearance of seborrhoeic dermatitis or of lupus erythematosus. Hardly ever does one see the typical heaped silvery scaling even in cases which have received no ointment therapy. The colour and the demarcation of the lesions are not always present but I have never to my knowledge seen psoriasis of the face without its occurrence elsewhere.

\* A lecture delivered to the Scunthorpe Division of the British Medical Association on November 3, 1937.

*Flexures*—Psoriasis affecting axillae, perineum, and under the breasts is not very uncommon, especially in seborrhoeic subjects. It is never covered with scales, but merely presents the salmon-red demarcated plaques which sometimes become slightly eczematous and moist or fissured. Psoriasis of these sites is usually very irritable, and particularly in the perineum, it may exist with little psoriasis elsewhere. The use of strong applications in these sites is limited, and this affords one of the occasions when I think it justifiable to employ x rays for psoriasis, the response as a rule being good. With psoriasis of the perineum it is most important to exclude any local irritant factors, particularly sugar in the urine, as a provocative cause of the eruption. In connexion with this one may mention psoriasis of the glans penis. Here the affection shows no scaling, and the red, well-demarcated thickened plaques can easily be confused with the so-called psoriasiform carcinoma, an intra-epidermal non-penetrating growth. It may be quite impossible to differentiate such a carcinoma from psoriasis clinically until there is evidence of psoriasis elsewhere. Even histological examination may present considerable difficulties to the expert.

*Palms*—Discrete nummular psoriasis of palms and soles very closely simulates a secondary syphilitic eruption of these sites. There is the same sense of infiltration, the same colour, and both may be associated with a widespread eruption and may have followed a throat infection. Examination of lesions elsewhere on the body, however, usually makes the diagnosis clear.

*Nails*—I think it is quite impossible to diagnose psoriasis of the nails unless there is evidence of psoriasis on other parts of the body. Any dystrophy or a ringworm or other infection of the nails may exactly simulate a psoriatic change. Pitting and distortion, thickening and opacities, and even heaping up of the nail-bed may occur in any of these states, but the pin-point pitting and the heaping up of the nail-bed causing eversion of the distal end of the nail are rather more characteristic of psoriasis than of other affections. Psoriasis almost invariably affects all nails of the hands and feet, as do most dystrophies, but infection, as in ringworm, more frequently involves a limited number of nails, no matter how long the infection may have existed. Unless the eruption exists elsewhere the most careful search for fungus should be made by nail-scraping and examination in liquor potassae. Since the disturbance which produces a psoriasis of the nails originates in the nail matrix it is obvious that local applications cannot be of much service. While internal remedies are of some limited value, x rays are undoubtedly of much use in treatment.

### Mixed Psoriatic Reactions

Though generally occurring as a simple and pure reaction, psoriasis may upon occasion cross with other reactions such as the toxic erythematous, seborrhoeic, lichenoid, and eczematoid. It is my experience that such mixed reactions nearly always form a type of psoriasis very difficult to treat and one that tends readily to relapse.

### TOXIC ERYTHEMATOUS PSORIASIS

This type of reaction is often widespread, it particularly affects the extremities, including the hands and feet, face and ears, and on casual examination suggests an ordinary toxic erythema of the multiforme type. Careful examination reveals that the eruption varies from a variety of lesion which appears to be pure and simple toxic erythema in everything except its persistence to lesions which, commonly occurring on the typical psoriatic sites, are true

psoriasis with the characteristic silvery scale and demarcation. These cases often follow some acute infective process, particularly an infection of the upper respiratory tract. Unlike an ordinary toxic reaction, they persist until taken seriously in hand, and even then are most difficult to treat. The lesions on the extremities often simulate those of an acute lupus erythematosus, and it is interesting that some of these appear to be helped by gold therapy. These cases should always be treated in bed, and should receive mild local applications. A search for any focus of infection which may have been responsible for the eruption should be made, and if possible it should be eradicated.

### SEBORRHOEIC PSORIASIS

This type of mixed reaction is more easily recognized, and has received more attention in the literature, particularly the French. It would seem that in these cases we are dealing with patients who have a tendency to react by psoriasis and in whom the provocative cause of the eruption has been a seborrhoeic outbreak. Though psoriasis commonly occurs on the usual sites it also in these cases involves the typical seborrhoeic sites, particularly the head, mid-chest and back, axillae, perineum and flexures, palms, and soles. Such cases are not particularly resistant to treatment, and should be attacked along the usual lines. Upon occasion, however, one meets with lesions of the so-called "seborrhoeid" type—usually few in number, well demarcated, and lichenified—which do not develop the characteristic scaling of psoriasis and which may be most resistant to treatment.

### LICHENOID PSORIASIS

This type is in my opinion a cross reaction between psoriasis and lichen planus. Section of a lesion histologically will show parts with the characteristics of psoriasis and other parts with the characteristics of lichen planus. The sites tend rather to be those of lichen planus—the inner thighs, the lower legs and forearms, both flexor and extensor—but this form of psoriasis is in my experience one of the most difficult with which to deal. It is, I believe, very uncommon, and in most cases may with confidence be diagnosed as one or other of the two affections at different times, but long observation convinces me that the reaction is really one of the mixed type. Treatment should, in my opinion, be essentially directed towards the psoriatic element, but I have sometimes found it quite impossible to clear these cases.

### ECZEMATOID PSORIASIS

It is natural that psoriasis, if it is irritable, should become eczematized by rubbing and scratching, and this does sometimes happen. The eczematization is usually of the chronic type—lichenification—and the superimposition of the lichenification on the psoriasis is fairly obvious. The combination does not, however, present any difficulties in treatment so long as some internal sedative tonic measures are adopted and local treatment at first is mild. I believe, however, that what we have in recent years been describing as "pustular psoriasis" is in fact a mixed psoriasis and acute eczematous reaction. This is a much more complicated and difficult problem, and calls for very careful approach and treatment.

In the acute cases the ordinary psoriatic eruption on trunk and limbs will on close examination disclose in places groups of minute pin-head sized lakes of sterile pus, but the feature is most in evidence on the hands and feet, where it is rather in the nature of a pustular pemphigus—some lesions being vesicular and some pustular, some pin-head-sized and others larger, but the walls

associated with and merging into a scaling erythema and the pompholyx lesions healing to leave brown macules which eventually clear without scarring.

In the chronic cases the eczematous element which is still occasionally vesicular but mostly pustular tends to consist of more uniformly pin head sized lakes to be confined to palms and soles and more particularly to involve thenar and hypothenar eminences. There is often some scaling erythema in these sites but quite half the cases show no typical psoriasis elsewhere and it is still a matter of dispute whether they are all examples of the same type of reaction and whether they are related to psoriasis or not. We may for the present call them persistent pustular pompholyx but I believe they are a mixed psoriasis and eczema reaction. The cause of such a reaction may upon occasion be too vigorous local treatment but more often it is the reaction to some internal disturbance. In a proportion of cases—perhaps 30 per cent—it appears to be the toxæmia from an acute or chronic infection usually of the upper respiratory tract particularly tonsillitis and gingivitis. The pustular psoriatic reactions from acute infection in my experience resolve readily with rest in bed attention to the acute infection and mild anti-psoriatic measures. The chronic reactions which often affect only palms and soles are not greatly or permanently influenced by local treatment—which again must be mild—but often clear with removal of a chronic infection if such can be found as in the tonsils. A number of these chronic cases however are I believe dependent upon constitutional disturbances other than toxic such as nervous and endocrine influences and may be quite incurable.

#### Ætiological Factors in Psoriasis

There is no evidence that psoriasis is an infection and very little I think to support the view recently expressed in Germany that it is due to a disturbance of fat metabolism. It is as true to say that we do not know the cause of psoriasis as it is to say that we do not know the cause of any other constitutional reaction—for example eczema or dyspepsia. We know in the first place that the tendency to psoriasis is often inherited; we also know that it disappears during severe illnesses from organic disease or with protein shock therapy. It is more important to remember that it tends to be provoked by minor maladies such as the acute specific fevers, tonsillitis, influenza or colds in the head. Pregnancy and nervous shock are other common causes of acute outbreaks of psoriasis while the more chronic states of physical and nervous debility as well as the vague influences of puberty and the menopause regularly determine the onset of exacerbations of this affection. It is very rarely that there is not some obvious precipitating cause for psoriasis but once provoked the reaction tends to persist like most skin reactions. When the patient is in the psoriatic state external injury will also bring out psoriasis at the site of injury.

All these features are characteristic of constitutional reactions in general and to them may be added the very definite susceptibility of psoriasis to suggestion and to climatic influences particularly to sunlight. I repeatedly observe the influence of suggestion in these cases and may cite as a good example a very extensive case approximating in part to the pustular type in a patient who had been affected for nine months. Ten days after I saw him I arranged to admit him to hospital as being valuable for teaching purposes and requested his doctor to make no alteration in treatment. On admission the patient was

practically clear and attributed his improvement to the ointment which he imagined I had prescribed. The importance of this aspect lies in the fact that one may obviously do harm by telling a patient with psoriasis that his condition is incurable and that treatment is useless. The susceptibility to climatic influences is more important for it is well known that in very warm and sunny climates psoriasis will disappear and will not reappear so long as the patient remains in that climate. It is obviously absurd therefore to suggest that treatment is useless.

#### Treatment of Psoriasis

Treatment of any constitutional disorder must take seriously into consideration the make up of the patient and his environment. The highest degree of physical and mental health is desirable and should be aimed at and excesses and variations from the normal should as far as possible be avoided. All this is very true of psoriasis but the need for the eradication of toxic foci is especially about the upper respiratory tract must be emphasized. These general aspects of treatment I will leave and will now deal with the particular.

In Leeds we have two routine lines of treatment sometimes instituted separately and sometimes in combination. The first is by tar baths and sunlight and this is the more cleanly and pleasant line of attack. A tar bath merely consists of the addition of 4 oz. to 8 oz. of liq. picis carb. to thirty gallons of water in which the patient soaks for ten minutes or a quarter of an hour. This is immediately followed by an exposure of the whole body to the ultra-violet lamp starting usually with a dosage of one minute at three feet distance to the front and the back. The dosage is very gradually increased usually by about a minute a week and rarely exceeds a maximum of four or five minutes. The addition of a little heat therapy as from a sollux lamp at the same time probably increases the efficiency of the treatment and certainly adds considerably to the comfort. With this treatment patients are advised to use a small amount of the following ointment at night time to remove scale.

R.	Acid salicylic	gr. v
	Hydragr. ammon	℥. i
	Liq. picis carb.	℥. i
	Paraff. moll.	ad. s. j.

It is in my opinion important that this treatment should be regular and be undertaken daily. In the majority of cases the psoriasis is cleared up in the matter of a few weeks sometimes in less than two weeks.

The second line of treatment is by cignolin (dioxanthranol, a synthetic chrysarobin substitute). Here all the psoriasis present, from head to feet, is thoroughly inunctioned twice daily with the following ointment.

R.	Cignolin	gr. j.
	Acid salicylic	gr. v
	Hydragr. ammon	℥. i
	Liq. picis carb.	℥. i
	Paraff. moll.	ad. s. j.

This ointment rapidly deteriorates and must be dispensed afresh every few days. My routine is to freshen it afresh every third day increasing the amount of the cignolin by 1 grain each time up to 4 grains or so depending on 6 grains depending on the reaction.

This treatment is most rapidly and thoroughly effective when the patient is kept at rest in bed or at least in a dressing gown existence so that he is constantly soaked in the ointment. Even baths may be avoided with advantage or be taken only at intervals of four or five days. The effect of treatment is to produce a reddening and

discoloration of the skin from the cignolin, the colour being a lilac tint, the garments in contact with the ointment are also lightly stained. If the patient cannot be confined to his room then the ointment therapy is applied thoroughly at night and he has a bath in the morning. Under ideal conditions this method will usually clear up an attack of psoriasis in two to three weeks. If this treatment is combined with light therapy the patient has a morning bath, followed by exposure to the ultra-violet lamp and by theunction.

So much for the particular treatment of the attack of psoriasis. More important than this, however, is the further treatment directed towards preventing relapses, for this is of greater benefit to the chronic sufferer than the temporary clearance of the eruption. In my experience it is of the utmost value for psoriatics to have a daily exposure to the ultra-violet lamp after the ordinary toilet bath throughout the year, or at least from September to May, and it is obviously most desirable that the patient should himself possess a lamp in his own home, so that the treatment may be added to his ordinary toilet routine without imposing any serious burden upon him. A small type of lamp is usually sufficient for this purpose, and though the cost is moderately high the expenditure is, it seems to me, a wise one in view of the fact that we are dealing with a malady which is likely to be an affliction for many years if not for life. The effect of this addition to the toilet routine is often to keep the patient completely clear of psoriasis. Even if this ideal is not attained the state of affairs is so vastly improved that life has an entirely different aspect for the chronic sufferer. It is undoubtedly the next best thing to being able to live in those climates where psoriasis does not exist.

If for reasons of expense or other circumstances this routine cannot be adopted an occasional clearance by a course of cignolin treatment, such as that indicated, is the most that can be done. In very obstinate cases it is sometimes helpful to give mild protein-shock therapy such as whole-blood injections, or intravenous injections of TAB, ten to twenty millions, on two or three occasions, at intervals of about five days. In some hands the use of intravenous gold injections is said to have been beneficial, but I have found it only occasionally of value. I very commonly, however, put patients with psoriasis on 1/8 grain of luminal, twice daily, after food, for long periods at a time, and believe that it does much to reduce the reactive tendency of the skin.

There are two further problems which these patients often put to the physician. They first ask, "Can you cure me, doctor?" to which I think the appropriate reply is, "No, but you can cure yourself by understanding the nature of the ill and the various remedies at your disposal." The next question is, "Should I marry?" and my own view is that psoriasis should not be regarded as a bar to matrimony, since it need not necessarily be passed on to the offspring, and, if passed on, can be adequately treated.

The Central Association for Mental Welfare has arranged a course for persons engaged in the training of mental defectives in occupation centres, institutions, or mental hospitals and for home teachers, to be held in London from July 4 to 23, also a course for officers of local authorities and local associations for mental welfare engaged in the ascertainment and supervision of defectives, during the same period. Full particulars of both courses may be obtained from the educational secretary, Central Association for Mental Welfare, 24, Buckingham Palace Road, London, SW1.

## THE STATE OF THE HEART IN GALL-BLADDER DISEASE

### A PERSONAL INVESTIGATION

BY

**SYDNEY M. LAIRD, B.Sc., M.D., F.R.C.P.S., D.P.H.**

*Assistant V.D. Officer, City of Liverpool formerly Assistant Resident Medical Officer, Mill Road Infirmary, Liverpool*

In considering this subject it is unfortunate that space does not permit of even a survey of the literature, but all the references are appended in the bibliography and the conclusions arrived at from their study are here presented.

1 Myocardial degeneration is not infrequently found in cases of cholecystitis and/or cholelithiasis.

2 The clinical manifestations of gall bladder disease may closely simulate disease of the heart particularly coronary artery disease, and the reverse is equally true.

3 The cardiac condition has been benefited by surgical treatment of the gall-bladder lesion in a proportion of the cases. In assessing these cases it is difficult to decide whether to attribute this amelioration of the cardiac manifestations to the removal of the noxious influence of a pathological gall-bladder or to the beneficial effect of the period of enforced rest in bed, a measure which must always favour a return to normal on the part of the myocardium.

4 Although a few examples of infective endocarditis occurring in cases of gall bladder infection have been reported, there has been no unequivocal proof that the endocarditis was secondary to the invasion of the gall bladder with pathogenic organisms and any murmurs developing during an attack of cholecystitis are to be regarded as belonging to the so-called 'functional' class, dependent upon dilatation of the chambers of the heart, and thus, indirectly, on the state of the myocardium.

5 Associated factors—for example, obesity, age, etc.—must be considered in assessing the possibility of any direct relation between gall-bladder lesions and heart disease.

6 The theory of submural streptococcal infection arising in the gall bladder substance and thence spreading to the myocardium via the lymphatic and blood channels, as suggested by Rosenow and supported by D. P. D. Wilkie and others, constitutes the most generally accepted explanation of the relation between lesions of the gall bladder and heart.

7 There is some evidence to suggest an increased incidence of lesions of the coronary arteries in the subjects of gall bladder disease.

8 The operative treatment of gall bladder lesion by cholecystectomy where possible, should not be delayed long and is not contraindicated by the presence of a cardiac lesion provided the state of the heart is compatible with the patient surviving the operation.

### The Present Investigation

This investigation is based on a personal study of six to five consecutive cases of gall-bladder disease admitted to the wards of Mill Road Infirmary, Liverpool. Although the study was essentially a clinical one, Graham's cholecystography, electrocardiograms, the urea clearance test, and the Wassermann test were routine measures. In assessment of the condition of the cardiovascular system was arrived at after consideration of the symptoms of cardiac insufficiency, clinical and electrocardiographic findings, and the patient's response to a standard exercise test. The diagnosis of gall bladder disease was based on the symptoms and clinical findings, together with evidence of gall-bladder dysfunction as detected by

cholangiography. In cases in which adequate absorption of orally administered dye from the stomach was in doubt cholangiography was repeated after the intravenous introduction of the radiologically opaque medium.

Operation was advised in the following types of case: (1) Cases with symptomatic clinical and radiological evidence of a pathological gall bladder in these cases slight or moderate myocardial damage was not considered a contraindication to operation. (2) Cases with symptomatic and clinical evidence of myocardial damage which on investigation revealed clinical and/or radiological evidence of a pathological gall bladder. Gross cardiac failure, extreme old age or severe respiratory disease constituted contraindications to operation in both groups of cases. Cholecystectomy under general anaesthesia was the operation of choice. The diagnosis of gall bladder disease was confirmed after operation by macroscopic and microscopic examination of the excised gall bladders. All cases treated by surgery were seen from time to time during convalescence and received full examination at the beginning of the fourth week after operation just before discharge. The patients were followed up the period elapsing between admission to hospital and the follow up examination varying in individual cases from two months to over a year.

#### Analysis of Cases

The series consisted of sixty five cases of disease of the gall bladder and biliary tract. The females numbered fifty eight and the males seven. Fifty of the patients had a clinical cardiac lesion while the remaining fifteen revealed no clinical evidence of a departure from normal in the state of the cardiovascular system. The incidence of cases per decade and the sex distribution are shown in Table I.

TABLE I—Showing the Relationship of Age, Sex and Cardiac Involvement in 65 Cases of Gall bladder Disease

Decade	Cardiac Lesion		No Cardiac Lesion	
	Female	Male	Female	Male
3rd	4	0	1	0
4th	5	1	5	0
5th	13	1	3	0
6th	11	3	3	0
7th	7	1	3	0
8th	3	1	0	0
Total	53	7	15	0

It is common knowledge that obesity is often present in cases of gall bladder disease and this factor was considered of importance as a possible explanation of any myocardial insufficiency in the cases of this series. Of

TABLE II—Showing the Incidence of Obesity and Cardiac Lesions in 65 Cases of Gall bladder Disease

Decade	Obesity and Cardiac Lesion	No Obesity but Cardiac Lesion	Obesity with n Cardiac Lesion	No Obesity or Cardiac Lesion
3rd	2	2	0	1
4th	2	4	0	3
5th	7	7	0	3
6th	5	9	2	1
7th	2	6	2	1
8th	2	2	0	0
Total	20	30	4	11

the sixty five patients twenty four were regarded as obese by estimating such factors as sex, age, height and weight. Table II shows that the incidence of cardiac lesions occurring in cases of gall bladder disease is greater than the incidence of obesity in the same series. This suggests that the obesity if a factor is not the whole explanation of the presence of cardiac lesions in these cases of gall bladder disease.

Fifty cases were followed up or were under observation until death occurred. Operation was performed in

TABLE III—Showing the Condition of the Heart after Operation in 27 Cases in which a Follow up Examination was obtained

Decade	Cardiac Cases with Obesity after Operation			Cardiac Cases without Obesity after Operation		
	Improved	Unchanged	Worse	Improved	Unchanged	Worse

TABLE IV—Showing the State of the Heart in the Quiescent Stage of Gall bladder Disease in 18 Unoperated Cases in which a Follow up Examination was obtained

Decade	Cardiac Cases with Obesity			Cardiac Cases without Obesity		
	Improved	Unchanged	Worse	Improved	Unchanged	Worse
3rd	0	0	0	0	0	0
4th	0	0	1	1	0	1
5th	0	0	0	0	1	1
6th	1	1	1	0	2	1
7th	0	1	0	0	3	0
8th	0	2	0	0	0	1
Total	1	4	2	1	6	4

forty and thirteen of these had cardiac manifestations. Cholecystectomy was carried out in thirty six cases. In twenty one one had exploration and drainage of the common bile duct and one a case of ulceration of the common bile duct had a cholecysto-duodenostomy performed. The latter two cases of disease of the common bile duct presented no manifestations of heart disease. Twenty eight of the thirty six cases treated by cholecystectomy were completely cured of the symptoms referable to the gall bladder, four cases were improved in this respect and four patients died. Table III and Table IV demonstrate the condition of the heart in twenty seven operated cases and in eighteen unoperated cases respectively of gall bladder disease with cardiac manifestations as determined at the follow up examination. In seven even mild cardiac decompensation was not considered to be a contraindication to operation in this series. The numerical difference between the cases showing improvement after operation and those showing improvement after the subsidence of the acute gall bladder infection but in which operation was not performed assumes significance as the unoperated cases did not necessarily present cardiac manifestations of such severity as to preclude any possibility of amelioration. The presence of obesity

in the operated cases appears to mitigate the chances of cardiac improvement. It is interesting to note that those patients with gall-bladder disease, without obesity, in which the cardiac condition deteriorated after operation were all over 40 years of age. These figures suggest that cholecystectomy provides a satisfactory means of obtaining amelioration of the cardiac manifestations occurring in cases of gall bladder disease and that the presence of such evidence of heart disease in some of these cases at least, does not constitute a contraindication to operation.

The duration of the symptoms of gall-bladder disease in relation to the incidence of associated cardiac lesions was considered worthy of investigation. This point is open to the obvious objection that disease of the gall-bladder may be latent in some cases, but it is difficult to suggest a more satisfactory basis for estimating the duration of the gall bladder lesion. Fifty-six cases of this series had had gall-bladder symptoms for more than six months, and of these cases forty-seven exhibited cardiac manifestations. There were nine cases in which the gall-bladder symptoms had developed within six months of admission to hospital, and of these only one-third had clinical evidence of heart disease—thus suggesting that the longer the disease of the gall-bladder is permitted to exist the greater is the possibility of cardiac manifestations appearing. It must be admitted, however, that this is equivocal evidence. The possibility of sepsis in foci other than the gall-bladder being an aetiological factor in the production of cardiac lesions was considered, and it was found that such foci were at least as frequent in the non-cardiac as in the cardiac group. Coronary thrombosis, diagnosed on clinical and electrocardiographic findings, occurred in eight cases, all of which showed some evidence of gall-bladder dysfunction. Three of these patients were male and five were female, while two cases occurred in the fourth decade, one in the fifth, three in the sixth, one in the seventh, and one in the eighth.

The forty-six cases of gall-bladder disease with cardiac lesions which were followed up were divided up into two groups: one in which the cardiac manifestations were absent on discharge from hospital or at the follow-up examination—that is, "temporary cardiac cases"—and another in which a heart lesion was still detectable on discharge from hospital or at the follow-up examination—that is, "permanent cardiac cases". Nine cases fell into the former group, all of which except one had been subjected to cholecystectomy, while the latter group consisted of thirty-seven cases, of which only eighteen had had surgical treatment. The incidence of obesity in these cases was two in the former group and fourteen in the latter. There were five cases in which the cardiac condition was improved on discharge from hospital but which showed further cardiac damage at the follow-up examination. All five cases have had cholecystectomy performed, three patients were obese and one was myxoedematous. The beneficial effect on the heart of the enforced rest in bed, before and after operation, was probably responsible for the temporary but unsustained amelioration of the cardiac manifestations in these five cases.

It was possible to compare the pre-operative, post-operative and follow-up electrocardiograms in forty cases of the series. This comparison revealed that the electrocardiogram was not in all cases an accurate indication of the state of the myocardium, and on occasion there was difficulty in correlating it with any change which the clinical cardiac manifestations might display. In cases in which coronary artery thrombosis had occurred, however, the electrocardiographic findings confirmed the clinical diagnosis and proved of definite value in prognosis.

The existence of gall-stones was proved at operation in twenty-nine of the forty cases in which operation was performed. Nineteen of these cases had cardiac manifestations, while the remaining ten had no clinical heart lesion. Cholecystitis without gall stones was found in ten of the forty operated cases, and eight of these had cardiac manifestations. These figures suggest that, within the limits of the present investigation, heart lesions occurred more frequently in cases of cholecystitis without gall stones than in cases of cholecystitis in which gall stones were a prominent feature. Jaundice was present in ten cases of this series, seven of them showing evidence of a cardiac lesion. In six of these latter cases the cardiac condition was permanent.

No personal investigation was carried out to determine the incidence of heart lesions in a group of cases in which gall bladder disease was thought to be absent, but the following figures are quoted from the paper by Schwartz and Herman:

*The Percentage of Heart Disease per Decade in 109 Patients Without Cholecystitis, Comparing it with 109 Patients With Cholecystitis*

Decade	Non Gall bladder Cases	Cholecystitis Cases
3rd	20	46.6
4th	8	41.6
5th	41.9	58.6
6th	54.1	79.1
7th	100	100
8th	80	100

The non-gall-bladder cases of Schwartz and Herman were chosen at random from medical cases in identical age groups which were treated in the wards of the hospital. We excluded no cases except those which were cardiac *per se*, as rheumatic fever, subacute and acute endocarditis, and so on."

For comparison the percentage of heart disease per decade in gall-bladder cases in the present series is added, as follows:

Decade	Percentage	Decade	Percentage
3rd	80	6th	82.3
4th	54.5	7th	72.7
5th	82.3	8th	100

It is doubtful whether these groups of cases are really comparable, also, the percentage of heart disease in the non-gall-bladder cases appears very high in the third decade if cases of rheumatic endocarditis were rigidly excluded. Even if the large percentage is accurate for cases without gall-bladder lesions, the proportion of heart lesions in gall-bladder cases is higher in the series of Schwartz and Herman, and even greater in the present series.

### Conclusions

From the preceding analysis of the cases of the present series the following conclusions seem possible:

1. Disease of the gall-bladder was commoner in females than in males in the proportion of 8 to 1.
2. The cases of gall-bladder disease occurred between the third and eighth decades inclusive, and were most frequent in the fifth and sixth decades.
3. The cases of gall-bladder disease often exhibited evidence of a cardiac lesion (77 per cent), and all the males and 74 per cent of the females were affected in this way.
4. Obesity occurred in 37 per cent of cases, and in the incidence of heart disease was greater than that of obesity in this series. It therefore appears that obesity is not the whole explanation of the occurrence of cardiac lesions in cases of gall bladder disease.

5 Foci of sepsis other than in the gall bladder were at least as frequent in the gall bladder cases with normal hearts as in those with evidence of cardiac damage

6 The cardiac lesion was temporary in some cases of gall bladder disease and permanent in others and some of the latter group displayed an unsustained amelioration of the heart condition after operation which was probably due to the beneficial effects of the enforced rest in bed

7 The incidence of heart lesions in cases of gall bladder disease was uninfluenced by the presence of jaundice

8 Coronary artery thrombosis occurred in 12 per cent of cases of gall bladder disease and on occasion may present difficulty in differential diagnosis

9 The electrocardiographic evidence was inconsistent in many cases of myocardial insufficiency when compared with the clinical condition of the patient but was of great value in cases in which coronary artery thrombosis had occurred

10 Cholecystectomy produced a cure of the gall bladder symptoms in 78 per cent. of cases in which this operation was performed and appeared to be a satisfactory measure for obtaining amelioration of the cardiac manifestations occurring in cases of gall bladder disease. The presence of similar heart conditions in cases of gall bladder disease does not constitute a contraindication to cholecystectomy. Fatal pulmonary embolism occurred as a post operative complication in 5 per cent of cases

11 There was some evidence to suggest that the longer disease of the gall bladder is permitted to exist the greater is the possibility of cardiac manifestations making their appearance. The early treatment of gall bladder disease by cholecystectomy thus appears to be indicated

12 From a study of this series of sixty-five cases of gall bladder disease the impression was gained that infection of the gall-bladder was a definite aetiological factor in the production of the myocardial lesions commonly found in these cases and that the presence of obesity though almost certainly a factor in some cases does not always explain the cardiac damage

I have to thank Dr L. Findlay, medical superintendent of Mull Road Infirmary, Liverpool for the many facilities which made this investigation possible and also for permission to publish the results obtained

## FOUR CASES OF MENINGITIS TREATED WITH PRONTOSIL

BY

F. H. JACOB, M.D., F.R.C.P.

Honorary Physician General Hospital Nottingham

The first two of these cases were treated by serum and prontosil the two others by prontosil only. In their clinical aspects all four were typical mild cases of cerebrospinal fever. In three of them Gram negative diplococci were found in the fluids but the weak point is that meningococci were not grown in any of the cases. Therefore the diagnosis is not proven. It was for this reason that I did not report them at the time. I had hoped for more undoubted cases so treated whether successfully or unsuccessfully would have been published before this. I am now recording these in the hope that they will serve as a late report from those who have more cases to treat.

The results in these cases were more rapid and complete than those I have usually obtained from serum. The treatment avoids the repeated puncture for administration of serum which is so trying a procedure to all concerned. The last case was punctured twice only—once for diagnosis and the other time to find if the fluid was normal. None of the patients was fully grown so the dosage was large but I felt that in this type of case an initial big dose was essential. All the cases were mild and would probably have ended in recovery without prontosil.

**Prontosil Reactions**—The late rise of temperature in Cases I and III may well have been instances of prontosil fever. The rash in Case IV was probably due to prontosil but in none of them was the patient ill. The blood well ate well slept well and said that they felt well.

## Case I

A boy aged 14 was admitted to hospital on February 19, 1937 having been ill for the past week with headache, general irritability and vomiting. There was definite head retraction and rigidity of neck and Kernig's sign was present. He was normally conscious. The cerebrospinal fluid was under pressure and was turbid.

*Pathological Report February 22*—Turbid xanthochromic fluid with a heavy deposit of pus. Chlorides 0.680 per cent, sugar absent, albumin 0.3 per cent. Films show large numbers of polymorphonuclears and a very occasional Gram-negative diplococcus, probably meningococcus.

The patient was treated by anti-meningococcal serum—intramuscular on February 19, intramuscular and intravenous on February 20, and by prontosil, two tablets (0.6 gramme) every four hours—that is 3.6 grammes (about 60 grains) each twenty-four hours—commencing February 21 and continued for one month.

He rapidly improved. Lumbar puncture on February 19, 20, 21, and 22, and again on March 17, showed that the fluid was clear, and the pathologist reported it to be normal. Before the end of the first week the headache and neck retraction had entirely disappeared. He looked well, and said that he felt well. He continued to have a slight pyrexia which in the third and fourth weeks sometimes reached 100° F, but remained in good health and without symptoms.

## Case II

A youth, aged 17, was admitted on April 26, 1937, with four days' history of headache and pain in the back and limbs, with vomiting for the last two days. He was quite conscious. Head retraction and neck rigidity were present. Kernig's sign was positive, and the cerebrospinal fluid was turbid and its pressure much increased.

*Pathological Report April 29*—Turbid xanthochromic fluid, with a large coagulum and heavy deposit of pus. Chlorides 0.720 per cent, sugar absent, albumin 0.2 per cent. Films show large numbers of polymorphonuclears and a very occasional Gram-negative diplococcus—probably meningococcus.

*Treatment*—He was given 10 c.c.m. of serum intramuscularly and 10 c.c.m. intrathecally on April 26, 10 c.c.m. intrathecally and 10 c.c.m. intravenously on April 27, prontosil on April 26—two tablets (each 0.3 gramme) four-hourly, increased to twenty tablets in the twenty-four hours on April 29, reduced again to twelve in twenty-four hours on May 2, and stopped on May 10. The patient made a rapid recovery.

## Case III

A youth aged 17, was admitted on May 7, 1937. Four days earlier his illness had begun with headache, vomiting, and stiffness in the neck. He was conscious. His head was retracted and his neck rigid. Kernig's sign was positive. The cerebrospinal fluid was under increased pressure and was turbid.

*Pathological Report May 8*—Fluid very turbid, xanthochromic with a heavy deposit of pus. Chlorides 0.690 per cent, sugar absent, albumin 0.2 per cent. Films show large numbers of polymorphonuclears and a very occasional Gram-negative diplococcus, probably meningococcus.

*Treatment*—This was by prontosil only—two tablets (each 0.3 gramme) every two hours (7.2 grammes in twenty-four hours) reduced on May 9 to every four hours, and stopped on May 17.

He very rapidly recovered, losing his headache, retraction and rigidity. During a second rise of temperature which occurred from May 14 to May 17, he said that he felt quite well. His cerebrospinal fluid was normal, and the blood culture negative. A blood count was not done.

## Case IV

A youth aged 16 was admitted on June 24, 1937, with five days' history of headache and shivering followed by drowsi-

ness, neck stiffness and vomiting. Head retraction and neck rigidity were present, and Kernig's sign was positive. Herpes labialis was also present. The patient was conscious. The cerebrospinal fluid was under pressure and turbid.

*Pathological Report June 26*—Very turbid xanthochromic fluid with a heavy deposit of pus. Chlorides 0.700 per cent, sugar absent, albumin 0.2 per cent. Films show large numbers of polymorphonuclears, no micro-organisms seen.

*Treatment*—Prontosil only—two tablets every two hours, reduced on June 26 to every four hours and stopped on July 3.

The patient very rapidly recovered, and the pathological examination on July 5 showed a normal cerebrospinal fluid. On July 7 he developed a generalized papulo-erythematous rash. This lasted only a few days, and he was discharged in good health on July 14.

[NOTE—The *Journal of the American Medical Association* of February 26, 1938 (p. 630), contains an article on "Sulfanilamide Therapy in Meningococcal Meningitis," in which Dr. Leon J. Willien reports an account of five cases, all cured by that substance. The author gives an initial subcutaneous injection of a large dose of the saturated (0.8 per cent) solution in amounts approximating 0.01 gramme per kilogramme of body weight—that is, 500 c.c.m. for a normal sized adult—followed by 15 grains (1 gramme) by mouth every four hours.]

## UNUSUAL COMPLICATIONS OF LABOUR

BY

H. BURT-WHITE, M.D., F.R.C.S., M.C.O.G.

Late Assistant Obstetric Surgeon, the City of London  
Maternity Hospital, Surgeon to Out-patients the  
Hospital for Women, Soho Square.

The two cases here described are grouped together for reasons other than their comparative rarity. At a first glance each appears to be a rare complication of labour, and there the similarity might appear to end. In one an annular portion of cervix was detached spontaneously during labour, while in the other an acquired vaginal septum obstructed birth. Their points of similarity probably lie in both aetiology and effect—a pre-existing inflammatory condition was certainly the cause in one, if not in both, and in each case there was a degree of obstruction to labour in the soft parts of the birth canal.

## Spontaneous Amputation of the Cervix during Labour

Spontaneous separation of part of the cervix in the course of labour would appear to be a rare accident. E. J. Decosta (1933) was only able to collect thirty-two cases from the literature between 1820 and 1933, and there was a long lapse of time between the reporting of the first two cases in America—that of Johnson was observed in 1851 and the second was recorded by Dorsett in 1927. Scott reported in 1821 the first case of annular separation of the cervix, which occurred in the case of a primipara, aged 36, after a long labour, the detached portion of cervix was expelled before the birth of the child. The next case was that of Carmichael, later reported by Power (1840). In this case there was some evidence of disproportion, for after the cervix had separated spontaneously embryotomy was necessary to deliver the child. If this peculiar accident of childbirth is to be viewed in its right importance it must be accepted that a large proportion of the very few recorded cases are proved examples of spontaneous separation. In fact unnecessary obstetric interference was probably the f-

mount factor and thus certain recorded cases do not properly belong to the spontaneous group. Some facts of interest are brought out in the following case history.

### Case I

A primigravida aged 26 was seen as an emergency case. Labour began on February 19 1930 and the patient was admitted to hospital at 3.40 p.m. apparently suffering from a severe degree of pain in the back. The general condition was good her temperature being 98° F her pulse rate 88 and her blood pressure 170/80 mm Hg. The uterus was larger than normal the foetus was in the first vertex position the head was engaging and the foetal heart was heard. The pelvic measurements were normal the cervix was one finger dilated and the membranes were intact. Combined abdominal and vaginal examination failed to show any disproportion. The membranes ruptured at 6 p.m. and examination revealed the cervix to be two fingers dilated.

On the following day (February 20) at 4 p.m. a further vaginal examination was made. The head had advanced and the absence of disproportion was confirmed. The cervix was three-fingers dilated and definitely not oedematous. On February 21 at 11 a.m. the head was found to have advanced little and a band of tissue was felt lying below and behind the foetal head. This was identified as an annular portion of cervix which was detached almost completely.

Subsequently at 5 p.m. on the same day the patient was delivered with forceps of a living male child. There was little difficulty in delivering the head but considerable difficulty with the shoulders which were unduly broad. There was considerable post partum haemorrhage due to the uterus being atonic and to torn vessels in the cervix. The annular portion of cervix was attached loosely to the uterus posteriorly over an area of between a quarter of an inch and half an inch. Slight traction completely detached the torn fragment. The cervix was sutured posteriorly and haemorrhage arrested to some extent. Laterally and anteriorly it was impossible to suture the cervix so the vagina and the remains of the cervix were plugged. At the time of delivery a swab was taken from the region of the cervix and subsequently showed a profuse growth of *Streptococcus pyogenes*. 30 c.c.m. of scarlet fever antitoxin were given immediately after delivery.

The patient was very shocked after delivery her pulse rate rising to 150 but after twenty-four hours it had fallen to 120 and the temperature was 99.6° F. From the second day onwards the puerperium was uneventful. The baby's weight at birth was 8 lb 9 oz the total duration of labour was sixty-two hours.

### SEPARATED PORTION OF CERVIX

It can be definitely stated that a cervix which was not oedematous at any time during labour and which felt normal became separated for about seven-eighths of its circumference in nineteen hours. The separated portion of cervix showed the external os to be dilated to a size of 2 inches by 1½ inches more cervical tissue was detached anteriorly and posteriorly than laterally. The detached portion was progressively thinner from the external os to the line of separation and there were scattered areas of haemorrhage into the substance of the cervix. Both surfaces were covered with irregular flakes of lymph and fragments of necrotic tissue.

Microscopically the epithelial covering of the cervix had for the most part disappeared. The blood vessels were dilated and engorged with blood and blood was also extravasated into the substance of the cervix which consisted mainly of fibrous tissue very little muscle and no elastic tissue was seen.

### SUBSEQUENT HISTORY

On vaginal examination of the patient three weeks after delivery the cervix had contracted down and felt normal. In fact it was difficult to believe that a portion had been detached. In August 1934 the patient was seen again. Since the labour in 1930 she had had no pregnancies, her periods were regular the loss remained unchanged and there was no pain. She had suffered intermittently from a slight vaginal

discharge but otherwise her health had been excellent. The child was progressing well and apparently had not suffered in any way.

### Comment

It would appear to be of prognostic importance not in this case as in all recorded cases the cervix tears at a point well below the utero-vaginal junction otherwise fatal complications would probably occur. In the case under discussion the separation of part of the cervix was discovered too late for any treatment. If a circular tear was diagnosed early it seems possible that a radial incision in the cervix opposite the tear might well prevent it extending further. Certain aetiological factors have been described in this rare condition and some can be accepted as possible in this case. Disproportion is an obvious predisposing cause first giving rise to oedema and later to necrosis and separation. In this instance however there was no disproportion and the cervix was not oedematous up to nineteen hours before delivery in the case of spontaneous separation in which there was no disproportion. The patient was a primipara and the membranes ruptured with the onset of labour. Twenty-nine hours after the onset of labour the cervix would only admit two fingers seven hours later no ring of cervix could be felt but behind the head an oedematous lip of cervix was palpated. Subsequently when it was decided to deliver the patient with forceps a ring of detached cervix slid out of the vagina. The patient died from a *B. coli* septicaemia. In this case the age of the patient and the early rupture of the membranes would appear to be the only definite factors.

Early rupture of the membranes must of course place an undue strain upon the cervix and in a high proportion of Decosta's (1935) series the membranes ruptured early or before labour started. In the case here recorded there was certainly a long labour and the membranes ruptured after fifteen hours when the os was two-fingers dilated. Normally during the first stage of labour cervical dilatation depends largely upon the upward traction of the longitudinal muscle fibres of the uterus and the downward pressure of the bag of water. With rupture of the hydrostatic bag there must be more pressure exerted through the foetus and subsequent advancement and dilatation are due to the direct pressure of the foetal head. In any event there must be undue pressure on the cervix and particularly in a case of disproportion. In disproportion the maximum pressure is naturally localized on that part of the cervix which is nipped between the foetal head and the pelvis. The absence of disproportion allows the foetal head to press evenly on the dilating cervix and thus one should not expect to find oedema present. This hypothesis undoubtedly explains the absence of oedema in the present case. Some degree of dilatation of the external os together with effacement of the internal os was also present and can be regarded as typical of this accident. The fact that dilatation is able to proceed to a certain degree rather tends to negative the possibility of any inherent rigidity being a factor.

Certain abnormalities of the form and fabric of the cervix may well be predisposing factors. The only abnormality in form to be considered is the length. Unfortunately no observer seems to have noticed this point before labour or to have had an opportunity of studying it in these cases. The matter remains one of conjecture the only evidence being the portion of tissue left behind. Three weeks after delivery my patient had a cervix of apparently normal proportions and yet the detached

annular ring represents a considerable amount of tissue. It may therefore be suggested that in this case the cervix was most probably abnormally long. In a case described by Fuh (1923) the findings were similar.

Could the cause of separation lie in the texture of the cervical tissue? This question is pertinent, but, unfortunately, the tissue separated is not ideal for exact microscopical examination. The normal cervix contains proportionately more connective tissue intermixed with smooth muscle and elastic fibres than does the body of the uterus. Other factors being equal, the ability of the cervix to dilate varies directly with the amount of muscle and elastic tissue as compared with fibrous tissue present. Couvelaire considered that the leucocytic infiltration frequently noted was indicative of pre-existing inflammation, which in turn gave place to fibrosis and rigidity. In the case described sections of the detached cervix appear to consist mainly of fibrous tissue infiltrated with blood, muscle fibres are scattered irregularly and in very small proportion, and elastic tissue is completely absent.

It is thus clear that in Case I the cause of rupture can be assigned to certain factors: (1) rupture of the membranes when the os was only partially dilated, thus bringing undue pressure upon the cervix, (2) an abnormally long cervix, and (3) a change in the fabric of the cervix, causing an increased proportion of fibrous tissue.

The incidence of cervicitis is so high and the accident of cervical detachment so rare that if previous inflammation be accepted as a definite aetiological factor there must be other contributory factors with which we are not yet sufficiently familiar.

This case also illustrates an interesting point in puerperal infection which has been recorded previously. A swab taken from the region of the cervix at the time of delivery produced on culture a pure growth of *Streptococcus pyogenes* which was proved to be virulent as regards experimental animals. The patient received 30 ccm of scarlet fever antitoxic serum and her temperature remained normal after the first day of the puerperium. Thus, she escaped puerperal sepsis in spite of the presence of a virulent strain of streptococci in the birth canal and severe damage to the soft parts. This must be attributed either to her own personal immunity or to the early use of serum. Whichever be accepted as the cause, the lessons to be learnt are identical in principle. The origin of *Streptococcus pyogenes* in the birth canal in this case is a matter of conjecture. This organism is not commonly present in the birth canal before labour. In 600 cases investigated I only found it present in three cases, and all possessed such a degree of immunity that no puerperal infection resulted.

#### Acquired Vaginal Septum Obstructing Labour

In the second case a vaginal septum sufficiently thick to obstruct delivery was acquired in a maximum period of two years. At the time of delivery the septum was imperforate, and after delivery by Caesarean section the pressure of the contracting uterus, stimulated by pituitrin, was insufficient to expel any lochia. That about forty weeks previously there must have been some orifice through which spermatozoa could penetrate is obvious. The method of dealing with this case may at first seem unusual, but the complications were also unusual and the end justified the means.

#### Case II

A patient aged 26 had a history of two previous pregnancies with normal labours at term. No positive history

of vaginal laceration could be elicited and there were no symptoms of such laceration having occurred, but no such had ever been made. The patient was seen in consultation with her own doctor on February 29, 1932. She had been in labour for eight hours with strong pains, on vaginal examination her own doctor had been unable to identify the cervix. The foetus was lying in the first vertex position and the head was well down in the pelvis. On vaginal examination the foetal head was easily felt through a septum but the external os could not be identified and even with a speculum no trace of the cervix could be found. A sound passed into the bladder reached almost to the blind apex of the vagina, and a finger was inserted into the rectum to a point only three quarters of an inch from the end of the sound. Owing to the close proximity of the rectum and bladder, however, it was thought dangerous to incise the vaginal septum lying below the foetal head.

A classical Caesarean section was performed and a live baby delivered. After removal of the placenta the lower uterine segment was carefully examined, visually and by palpation, but no part of the os could be identified. After suturing the uterus and abdominal wound, the patient was placed in the lithotomy position. No blood had passed into the vagina, and other search for the cervix was fruitless. Pituitrin, 5 units, was given four hourly; each injection produced pain referred to the uterus, but still no lochia escaped. As the pituitrin produced an unpleasant degree of pain and as there was also abdominal distension not relieved by enemata, eserine sulphate, grain 1/32, and strychnine sulphate, grain 1/32, were substituted. These also produced abdominal pain and were therefore discontinued. The height of the uterus remained unchanged until the eleventh day of the puerperium, during the twelfth and thirteenth days the level rose by one inch, and continued to rise till the fifteenth day. Following this the height gradually fell, till it reached a level halfway between the symphysis pubis and the umbilicus on the twentieth second day of the puerperium. During the whole puerperium there had not been any escape of lochia and the temperature and pulse remained normal.

#### EXCISION OF VAGINAL SEPTUM

On the thirtieth day after delivery the patient was examined under an anaesthetic in the lithotomy position. The vaginal vault was seen to be blue in colour and bulging. The cervix was incised and about 10 oz of chocolate coloured infected blood escaped, the uterus was then carefully washed out at a low pressure. The incised membrane was found to be very tough and about a quarter of an inch thick, a circular area of one and a quarter inches diameter was removed. Adherent to the upper surface of this membrane the external os was located and found to be two fingers dilated, the internal os still seemed to be fully taken up. Recovery from the operation was uneventful and the lochia ceased twelve days later. The patient was again examined after an interval of eight weeks. The uterus was then found to be fully involuted and the orifice in the vaginal septum had contracted down so as to admit only one finger. Under an anaesthetic more of the septum was removed and a vaginal dilator was left in position for a week, being removed and replaced daily. Microscopical examination showed the septum to consist of dense fibrous tissue covered on its upper and lower surfaces with stratified squamous epithelium.

#### Comment

This case certainly resembles those in which an inflammatory condition of the cervix or vagina has caused shrinking of the covering mucosa, subsequent adhesion of the raw surfaces, and finally organization of the inflammatory tissue. The end-result is an imperforate cervix or vagina. This condition is probably what is once known as the *conglutatio orificii* a term of Naegele. Very few of these cases have been recorded. Croft and Claye (1928) described that of a woman who had passed through four normal pregnancies, there had been

marked degree of prolapse and ulceration of the cervix. At the time of the fifth labour the only trace of the external os was a slight linear scar. A case more closely resembling the one described here was recorded by Kanter and Klawans (1930). They reported a case of vaginal atresia occurring rapidly after an operative delivery. In such cases the pelvic floor and bladder are greatly relaxed so that the anterior and posterior vaginal walls come to lie in close approximation. In their case a woman was delivered on June 15 1929. The delivery was with forceps and without any anaesthetic; no attempt to repair any tears was made. The temperature and pulse were normal in the puerperium but no lochia were passed after the third day. The patient was seen on September 30 of the same year. There was then found to be atresia of the vagina at the level of the entrance of the urethra into the bladder. In this case the degree of damage to the vagina was not known and strong antiseptics employed at the time of delivery may have played a part in giving rise to the condition. This case demonstrates well how quickly atresia of the vagina may occur and the strength of the septum so formed—sufficient in this instance to retain the lochia after the third day of the puerperium.

In Case II the exact aetiological factors concerned in producing the septum must remain to some extent obscure even though the field of possible causes is considerably restricted. The history of previous labours in itself at first seems to exclude any congenital abnormality as a possible contributory factor but this must be considered later. Some trauma to the vagina in the course of the previous labour might have been the starting point of such a septum. If there were trauma then one would expect it to have been fairly severe and to have produced symptoms not easily overlooked. Yet the previous labours and puerperia were normal and the only symptom was a slight and persistent vaginal discharge. If the septum began to develop soon after the second labour then one would have expected some obstruction to the flow of blood at the periods. Unfortunately the flow was always small and no change was noticed except a slight increase in pain during the periods. This pain may point to some obstruction arising in the vagina.

It is thus apparent that although trauma and infection either jointly or separately were the responsible factors yet there is no real proof of this. One is forced therefore to consider afresh a congenital theory. Perhaps there was a congenital narrowing or a partial septum present in the upper part of the vagina and a degree of trauma and infection unlikely to cause trouble in a normal vagina were the final factors in this case. This view is supported by the type of septum found which was well defined remarkably thick and resistant and did not seem to consist of recently organized granulation tissue. Further the vagina below the septum appeared quite normal and there was no evidence of long standing infection anywhere in the genital tract. The total disappearance of an orifice during pregnancy also offers a remarkable picture; it is of interest to consider how small or large it was at the time of conception. The increased vascularity of the vagina during pregnancy would no doubt accelerate the closing of the septum provided the edges were not epithelialized. This case also illustrates the fact that the retention of the lochia after labour need not cause any anxiety. At the time of the Caesarean section the degree of asphix was good, and in the absence of any infection the retention of a large volume of lochia for a considerable period had no effect on the temperature, the pulse rate or the general condition of the patient.

## UNUSUAL PHYSICAL SIGNS IN LOBAR PNEUMONIA

BY

G. S. ERWIN, M.B.

Resident Medical Officer, Brompton Hospital

AND

R. J. MCGILL, M.B.

Assistant Resident Medical Officer, Brompton Hospital

Lobar pneumonia may present in place of the classical physical signs abnormal findings so conclusive to the diagnosis even when the onset symptoms and temperature are conclusive. These perplexing features would seem to require explanation and this can be found only in physiological and pathological changes in the underlying lung since physical signs in themselves are inconclusive in groups are not conclusive proof of any particular disease. Thus the consolidation or pneumonia due to alveolar exudate is usually evidenced by dullness to percussion and by bronchial breathing and these are the accepted signs of the disease. When alveolar exudation is complicated by bronchial filling there is produced a different group of physical signs—those of a solid lung with a blocked bronchus. A complete absence of vocal sounds is discovered together with other signs suggestive of a moderate accumulation of fluid.

### Three Illustrative Cases

A patient recently observed by us at the Brompton Hospital developed on the second day a temperature of 101.4° Fahrenheit with absent breath sounds at the right base and dullness to percussion. Bronchial breathing at the left base, the apex, and not being displaced. Two days later an x-ray film showed consolidation at both bases more marked on the right, but with no clear evidence of fluid. After ten days the fever subsided but consolidation was not until the fourteenth day that bronchial breathing was first detected at the right base. Subsequent x-rays demonstrated gradual clearing of the consolidation. We believe that the physical signs first found at the right base were those of pneumonic consolidation together with blockage of the main bronchus by a sputum plug, expectoration of which a fortnight later allowed air entry and the production of bronchial breathing. This supposition was confirmed by bronchography on the tenth day when it was demonstrated that though the main bronchus of the right lower lobe was patent all the secondary and tertiary bronchi were blocked. Repetition of the bronchography prior to the patient's discharge showed the presence still of a little sputum in the practical purposes the bronchi of the lower lobe were normal.

Another pneumonic patient exhibited the classical appearance of right basal consolidation, but though the percussion note was dull no breath sounds could be heard over

ient

rest  
piece are  
adjusted to the  
my in the manner  
by Henning as follows  
) The upper thigh is held  
when the knee pillar in front  
and the back rest so that the  
patient cannot roll over the lower  
knee is flexed in front of the knee  
pillar and the foot is brought  
behind the foot pillar. Comfortably  
locked in this way the patient's  
left leg prevents him from slipping  
down the table when it is tilted  
and allows the abdomen to be free  
of all pressure. The head section  
of the table proper is then dropped  
and the head rest of the attach-  
ment is swung in to support the  
head and adjusted for height and  
in the horizontal plane in both  
axes. The shoulder stop carried  
on the head rest is adjusted to  
prevent the patient's lower shoulder  
from twisting forwards.

It is explained to the patient that  
he is being thus securely held in  
order that the table can be tipped  
during the examination without  
fear of his slipping and he is  
encouraged to relax his body  
against the supports. The instru-  
ment can then be passed without  
other assistance although a second  
person to hold the patient's head  
and a nurse to hold his hands will  
help if available to increase his  
confidence.

The details of the table top are  
shown in the photographs open  
on the table without attachments  
with attachments in position with  
the patient upon it and finally  
folded up ready to be carried  
away. It is made of two padded  
sections hinged together in the  
middle for ease of portability.  
The combined head rest and  
shoulder stop is carried in a slotted

FIG 1—Attachment in position on operating table read for patient. All supports are removed and the head rest (X) is swung clear to allow the patient to lie on his back to anaesthetization of the throat.

FIG 2—Gastroscope attachment complete. (1) Foot pillar (2) knee pillar (3) back rest with adjustable arm (4) head rest (5) shoulder stop

length, and swivels at the attached end so that it can be swung laterally as required. The height of the head cushion is controlled by the wheel beneath it. The foot and knee pillars slot into keyways which allow longitudinal and transverse adjustment respectively, being clamped in position by a butterfly screw on top of each. The back rest fits into a transverse carrier, which can be adjusted for position across the table by a screw action actuated by a handle.

The apparatus is made by the Genito-Urinary Company, and I would like to take this opportunity of thanking Mr R Schranz for his co operation and help in the experimental stages of construction. I also wish to express my appreciation of the support given by the British Medical Association in this work.

FIG 3—The patient in position. Note that the top section of the operating table has been dropped to allow the head rest to be swung into position.

G Hertzberg (*Nord med Tidskr* February 5, 1938 p 213) challenges Joslin's dictum that "diabetes is largely a penalty of obesity and the greater the obesity the more likely is Nature to enforce it." At the Rikshospital in Oslo the author has systematically weighed 400 consecutive cases of diabetes admitted to hospital in the period from the beginning of 1931 till the spring of 1935. The height of each patient was also measured, and standard weights of normal Norwegians of various heights and ages served as controls, any weight within 10 per cent of the normal whether above or below it was considered as normal. Nearly half of the juvenile diabetics were underweight, while about a third were overweight. About 20 per cent of the men were underweight while 33 per cent were overweight. Of the women about 16 per cent were underweight and 55.7 per cent were overweight. As in Joslin's experience, the proportion of underweight cases was higher in young than in old patients and this difference was greatest when the discrepancy in age was most marked. In every age group however the Norwegian diabetics were lighter than Joslin's American patients. Indeed, as one of Hertzberg's tables shows, there was no striking difference between the normal weight and that of his diabetics at the beginning of their disease. He concludes that his observations fail entirely to confirm Joslin's assumption that overfeeding plays a dominant part in the aetiology of diabetes. The Norwegian figures suggest that the severity of the disease was on the whole inversely proportional to the patient's weight before and at the time of the development of the diabetes for the insulin taking patients—that is the worst cases—were numerically best represented among the underweight group. Half of the overweight patients could dispense with insulin but this applied to only one-ninth of the underweight patients.

## Clinical Memoranda

### Fatal Haemorrhage into Rectus Abdominis Muscle during Pregnancy

A case of severe haemorrhage following rupture of a rectus muscle appears to be worth recording in view of the fact that it must be unusual.

#### CLINICAL HISTORY

A multipara aged 30 who had had five children all weighing 10 to 12 lb was expecting her sixth child on February 17. She had always been a healthy woman though very stout and during the pregnancy no albumin was present in the urine. Just after Christmas she had a cough and complained occasionally of a pain in the left upper part of the abdomen. The husband stated that it was a dry cough and that his wife had to hold her abdomen while coughing. At 11.30 p.m. on February 7 following a bout of coughing she had a sudden severe pain in the left side of the abdomen and felt that she was dying.

She was seen by a doctor at 9 a.m. on February 8 and was transferred to the Farnham County Hospital. On admission she was extremely pallid and collapsed; the pulse was scarcely perceptible and there was marked respiratory distress with slight cyanosis. Her condition suggested a severe haemorrhage. The abdomen was very large but not tense or rigid or so far as could be judged tender. The uterus was large and flaccid. The wall seemed to be thin and the outline was ill defined. Foetal parts could be plainly felt nearly up to the costal margin on the right side but not in the upper left quadrant where there was an ill defined resistance. There was nothing to suggest free fluid in the abdomen.

It was decided to give a blood transfusion and open the abdomen but although a donor was obtained and grouped within half an hour the patient died before this could be done.

#### PATHOLOGICAL FINDINGS

At the post mortem examination the left rectus sheath was found to be grossly distended with blood and resembled a large sausage-shaped balloon extending from the pubes to the lower ribs. Three pints of blood and blood clot were removed from the sheath and a long jagged tear was found in the posterior surface of the muscle belly at the junction of its lower and middle thirds. Small tears and evidence of old haemorrhages were found in the upper segments of the muscle. Owing to laceration the end of the ruptured vessel was not found but it seems probable that it was the deep epigastric artery as it is unlikely that such severe haemorrhage could have occurred from a vein.

The uterus which was normal except for rather an excess of liquor amni contained a normal male child weighing about 9½ lb. The liver and heart showed some evidence of fatty degeneration but the remaining organs appeared healthy.

#### COMMENTARY

The rectus muscle had obviously been weakened by the combination of several large pregnancies and a very fat pendulous abdomen and had given way under the strain of coughing. Several small haemorrhages had occurred in the month preceding death but the cough on February 7 had caused an extensive rupture of the muscle and had opened up a big vessel which had bled profusely. It was unfortunate that she did not reach hospital until it was too late for anything to be done.

In the *Bulletin of the Johns Hopkins Hospital* (1937 61: 293) T. S. Cullen and Max Brodel give a good account of lesions of the rectus abdominis muscle simulating an

acute intra abdominal condition. They state that haemorrhage into or beneath the rectus abdominis muscle is rare. It may take place in any part of the muscle but it is usually below the umbilicus. In some cases the muscle is torn in others branches of the deep epigastric artery or vein have ruptured in still others there has been no rupture of the muscle and also a tearing of one of the blood vessels.

The posterior sheath of the rectus is absent in its upper portion consequently where the bleeding is below the umbilicus the blood usually lies between the muscle and the peritoneum. This causes peritoneal irritation and produces symptoms simulating in nearly every particular those of an acute abdominal lesion. Occasionally the rupture of the rectus muscle has been caused by direct trauma but usually however the patient has for some time been suffering from some debilitating disease such as typhoid or influenza, and a slight exertion has been followed by sudden abdominal pain with the development of a haematoma. Cases are quoted where rupture of the rectus has been associated with gall bladder disease and febrile disease as well as pregnancy.

### Chemotherapy of Virus Infections

In view of the results obtained by Rosenthal, Woolf and Bauer (1937) and by Dochez and Slanetz (1938) suggesting that drugs related to sulphanilamide had some curative effect on animals infected with influenza, choriomeningitis and distemper virus respectively, a series of experiments has been carried out to test the effect of these drugs on virus influenza in mice. Our experiments have been confined to para aminobenzenesulphonamide, 4,4-diaminodiphenylsulphone, 4-benzylideneamino-aminodiphenylsulphone, sodium sulphanilatesulphanilate and 4,4-diaminodiphenylsulphone glucoside.

Groups of mice weighing 10 to 12 grammes usually ten in a group were infected intranasally under ether anaesthesia with 0.05 c.c.m. of falling droplet containing  $10^{-4}$  or  $10^{-5}$  of sterile glucose containing virus (WS strain titre  $10^6$  m.d.c.m. per c.c.m.). Immediately after and on each subsequent day the virus was given by mouth a dose of drug which experiment had shown was well tolerated by uninfected animals. All controls were provided. After a week those animals which had not already died of influenza were killed and the degree of influenzal consolidation of their lungs noted.

#### Results

Four hundred mice were used. In no case was there any reduction in the mortality of treated animals infected with doses of virus fatal to the controls. Indeed animals treated with para aminobenzenesulphonamide and 4-benzylideneamino-aminodiphenylsulphone died sooner and showed a higher mortality and more extensive lung lesions at all infective dilutions of virus than did the corresponding controls. Between animals treated with 4,4-diaminodiphenylsulphone or sodium sulphanilate and the controls there was no significant difference. Although animals treated with 4,4-diaminodiphenylsulphone glucoside after infection with large doses of virus showed no advantage over the controls the difference appeared to be a small but consistent and significant difference in favour of the treated animals when the virus inoculum was reduced to  $10^4$  or  $10^5$  m.d.

It is possible that drugs of the sulphanilamide group may be used to treat the secondary infections in human influenza. These experiments suggest that care should be exercised in the choice of the drug used, and that of those tested by us 4'-diaminodiphenylsulphone glucoside is the drug most worthy of trial.

## Digitalis Poisoning in a Child—Recovery

The case reported below is a further example of the risk of dangerous drugs being carelessly left where children can obtain them. The interest in this record lies in the history of the effects of a single dose of 1/50 grain of digitaline upon a child of 3 years, and the response to treatment with atropine and strychnine, it was noted that atropine was more effective than strychnine, and both than caffeine sodium benzoate, in raising the pulse rate from the state of digitalis bradycardia. There is also an indication of the time required for elimination of the drug.
